LIST OF CONTRIBUTORS TO VOLUME CXX.

Those whose names are marked with an asterisk have contributed editorial articles.

AHLSWEDE, H. EDWARD, M.D., Buffalo, N. Y.
ALMOUR, RALPH, M.D., New York.
AMSTER, J. LEWIS, M.D., New York.
ANDREWS, EDMUND, M.D., Chicago.
APFEL, HARRY, M.D., Brooklyn, N. Y.
AULDE, JOHN, M.D., Philadelphia.

*BAAR, GUSTAV, M.D., F.A.C.P., Vienna, Austria.
*BANCROFT, FREDERIC W., M.D., New York.
BARKER, LEWELLYS F., M.D., LL.D., Baltimore, Md.
BARNES, GEORGE EDWARD, B.A., M.D., Herkimer, N. Y.
BARTLE, IRA D., M.D., North Bend, Ore.
BASTEDO, WALTER A., M.D., New York.
BEINFIELD, HENRY H., M.D., Brooklyn, N. Y.
BEL, GEORGE S., M.D., New Orleans, La.
BELL, F. MCKELVEY, M.D., New York.
BENJAMIN, HARRY, M.D., New York.
BESSER, HERMAN, M.D., New York.
BIDDLE, A. GRAHAM, M.D., New York.
BISHOP, LOUIS FAUGÈRES, M.D., Sc.D., F.A.C.P., New York.
BLAND, P. BROOKE, M.D., Philadelphia.
BLAUNER, SAMUEL A., M.D., New York.
*BOAS, ERNST PHILIP, M.D., New York.
BONIFIELD, C. L., M.D., Cincinnati, O.
BOORSTEIN, SAMUEL W., M.D., F.A.C.S., New York.
BOSTON, L. NAPOLEON, M.D., Philadelphia.
BRAGMAN, LOUIS J., M.D., King's Park, Long Island, N. Y.
BRAHDY, M. BERNARD, M.D., New York.
*BRINK, LOUISE, Ph.D., New York.
*BROWN, MABEL WEBSTER, A. B., New York.
BROWN, SANGER, 2ND, M.D., New York.
BRYANT, W. SOHIER, M.D., New York.
BUCHANAN, J. ARTHUR, M.D., M.S., Brooklyn.
BUSCH, WERNER, M.D., D. Nat. Sc., Hamburg, Germany.
BUSH, A. D., M.D., Emory University, Ga.
BYRD, HIRAM, M.D., Bradentown, Fla.

CARTER, C. EDGERTON, M.D., Los Angeles, Cal.
CARTER, WILLIAM WESLEY, M.D. F.A.C.S., New York.
CIPES, BERNARD J., D.D.S., Mount Vernon, N. Y.
*CLOUTING, CHARLES A., M.D., London, England.
CLUTE, HOWARD M., M.D., Boston.
COHEN, SAMUEL, M.D., Philadelphia.
CORNWALL, EDWARD E., M.D., F.A.C.P., Brooklyn, N. Y.
*CUMSTON, CHARLES GREENE, MD., Geneva, Switzerland.
CUNNINGHAM, JOHN H., M.D., Boston.

DEUTSCHMAN, D., M.D., New York.
*DIAMOND, M., D.D.S., New York.
*DONNELLY, WILLIAM HENRY, M.D., Brooklyn, N. Y.
DOUGLAS, GILBERT FRANKLIN, M.D., Birmingham, Ala.
DUNCAN, HARRY A., M.D., Philadelphia.
DUTTON, W. FOREST, M.D., Philadelphia.

*EINHORN, MAX, M.D., New York.
ELA, ALFRED, Boston, Mass.
EPSTEIN, J., M.D., New York.
*ERDÖS, ADOLF, M.D., Oradea Mare, Transylvania, Roumania.

FERGUSON, BURR, M.D., Southampton, England.
FISHER, WILLIAM A., M.D., Baltimore, Md.
FITZPATRICK, JULIA, B.A., Rochester, Minn.
*FOSTER, MATTHIAS LANCKTON, M.D., New Rochelle, N. Y.
*FOX, HOWARD, M.D., New York.
*FRIDENBERG, PERCY, M.D., New York.
FRIEDENWALD, JULIUS, M.D., Baltimore, Md.
FRIEDMAN, JOSEPH, M.D., Brooklyn, N.Y.
FRIEDMAN, JOSEPH, M.D., New York.
FRIEND, HERMAN, M.D., New York.
FROSCH, H. L. B.S., M.D., New York.

GAGER, LESLIE T., M.D., New York.
GARAI, FRANK, M.D., New York.
GETTINGER, J. H., M.D., New York.
GIBBON, ROBERT L., M.D., Charlotte, N. C.
*GILLETT, A. SCOTT, F.R.C.S.E., London, England.
GILLETTE, NORRIS W., A.B., M.D., Toledo, Ohio.
GOECKERMAN, WILLIAM H., M.D., Rochester, Minn.
GOLDSTEIN, HYMAN, M.D., Camden, N. J.
GOLDSTEIN, LEOPOLD, M.D., Camden, N. J.
GOLOB, M., M.D., New York.
GOODMAN, HERMAN, M.D., New York.
GORDON, ALFRED, M.D., Philadelphia.
GORDON, MARK, M.D., Brooklyn, N. Y.
GRANT, FRANCIS G., M.D., Philadelphia.
GREENBAUM, SIGMUND S., M.D., Philadelphia.
GREENBERG, DAVID, M.D., New York.
GREENFIELD, SAMUEL D., M.D., Brooklyn, N. Y.
*GWATHMEY, JAMES TAYLOE, M.D., New York.

HALL, T. PROCTOR, M.D., Vancouver, British Columbia, Canada.
HALLILAY, W. H., I.M.S., London, England.
HALPERT, HENRY, M.D., Scranton, Pa.
HANKINS, F. H., Northampton, Mass.
HARKAVY, JOSEPH, M.D., New York.
HARRIS, WILLIAM L., M.D., Providence, R. I.
*HANET-ARCHAMBAULT, G., M.D., Meudon, France.
*HENDERSON, J. T., Pietermaritzburg, Natal, S. Africa.
HERTZBERG, G. R. R., M.D., F.A.C.S., Stamford, Conn.
HERTZBERG, REINHOLD F., A. B., Stamford, Conn.
HEYD, CHARLES GORDON, M.D., New York.
HUBBARD, L. D., M.D., Washington, D. C.
HUBERT, LOUIS, M.D., New York.
HUTTON, JAMES H., M.D., Chicago.
HYMANSON, A., M.D., New York.

JABLONS, BENJAMIN, M.D., New York.
JACK, GEORGE N., M.D., Buffalo, N. Y.
*JAHSS, SAMUEL A., M.D., New York.
*JECK, HOWARD S., M.D., New York.
*JELLIFFE, SMITH ELY, M.D., New York.
JENNINGS. ALPHEUS FELCH, M.D., Detroit, Mich.
JENNINGS, CHARLES GODWIN, M.D., Detroit, Mich.
JONES, CLEMENT R., M.D., F.A.C.P., Pittsburgh, Pa.

KAHN, I. S., M.D., San Antonio, Texas.
*KANTOR, JOHN LEONARD, M.D., New York.
KAY, H. M., M.D., Madison, Wisconsin.
KELLER, HENRY, M.D., New York.
KENNEDY, WILLIAM H., M.D., New York.
*KERBY, ERNEST, M.D., New York.
KILDUFFE, ROBERT A., M.D., Los Angeles, Cal.
KIRBY, FRANK B., M.D., Chicago.
KLAPPER, HARRY, M.D., White Plains, N. Y.
KLAUS, HENRY, M.D., Weehawken, N. J.
*KNIGHT, C. P., Surgeon, U.S.P.H.S., Canal Zone.
*KNOPF, S. ADOLPHUS, M.D., New York.
KOUINDJY, P., M.D., Paris, France.
KROBALSKI, JOSEPH, M.D., New York.
KROSS, ISIDOR, M.D., New York.

LAVENDERA, MIGUEL, M.D., New York.
LAVERTY, EDWARD CALVIN, M.D., Louisville, Ky.
LE FEVER, H. E., A. B., Glouster, O.
LEVIN, OSCAR L., M.D., New York.
*LIEB, CLARENCE W., M.D., New York.
LIVINGSTON, W. H., M.D., New York.
LLEWELLYN, LLEWELLYN JONES, M.B. (Lond.), London, England.

*WRIGHT, JONATHAN, M.D., Pleasantville, N. Y.

INDEX TO VOLUME CXX.

PAGE.

ABDOMEN, cutaneous hyperesthesia in acute disease of..... 360
treatment of acute conditions of..... 361
upper, pain in 469
postoperative infection of..... 473
Abdominal operation for retroversion, afterresults of 518
spasm with epidemic encephalitis..... 468
Abdominoscopy 360
Abortion 91
experience with one thousand cases..... 520
febrile, treatment of..... 521
rapidity of sedimentation of erythrocytes in 521
Abscess, brain, with pathological observations 151
Acetonemia in children..... 626
Acid, acetylsalicylic, effect of, on cardiac irritability 255
free, determination of, in gastric juice by titration of the indicator..... 362
lactic, excretion of, in carcinosis..... 470
Acidosis and rickets..... 625
of children, dry diet in..... 489
Addison, Thomas, biographical sketch of.. 339
Addison's anemia and subacute combined degeneration of spinal cord..... 468
Adenomata, encapsulated, of thyroid..... 197
Adrenal virilism complicated by diabetes insipidus 573
Adrenalin, absorption of..... 255
in manual delivery of placenta..... 197
Age and physical labor..... 558
Ahlswede, H. Edward. (See supplement index.)
Ala deformity, operation for..... 72
Alcohol and carbolic acid..... 259
Alcoholic intoxication and carbon dioxide.. 185
mental diseases 239
poisoning 353
Alcoholism, mental states in.....239, 414
Alexander-Adams operation, results with.. 520
Allergic high blood pressure controlled by epinephrin 596
Allgemeine Krankenhaus 242
Almour, Ralph. (See supplement index.)
Alum oil spray, in nasopharyngeal conditions 26
Amenorrhea, constitutional significance and treatment of 520
American Heart Association..... 501
Amputations, new retractor for..... 171
Amster, J. Lewis. (See supplement index.)
Anaphylaxis 41
in relation to clinical medicine..... 110
Andrews, Edmund. Choice of operation for inguinal hernia 57
Anemia in nephritis with nitrogen retention 467
chronic, and related conditions 421
desiccated spleen and red bone marrow in treatment of..... 281
pernicious 467
and sprue 467
in relation to hemolytic disorders..... 467
platelet count in by Thomsen's method 468
with degeneration of spinal cord..... 468
sickle cell 467
Anemias, of childhood, germanium dioxide in treatment of..... 468
Anesthesia by chloroform in asphyxia of child during delivery 521
ethylene 523
in bad operative risks 522
in intracranial surgery 522
intravenous 523
local, and goitre risk..... 198
for dental, oral, nose, and throat surgeons 220, 279
in minor gynecological operations.... 518
of splanchnic nerve..... 151
paravertebral, in kidney surgery..... 523
pure nitrous oxide oxygen..... 523
regional, in gynecology..... 522
sacral 523
spinal 523
Aneurysm of renal artery..... 254
Angina pectoris 142
blood pressure and heart action in sleep and dreams in relation to.... 253
surgery in 311, 574
syphilis in 574
Aniline dyes in treatment of infections.... 437
Animal and man..... 84
Animals, diseases of..... 183
Ankle joint, compression leverage fractures of 50
Ankylosis of joints, mobilization in treatment of 306
Anomalies in laryngology 223
of intestinal rotation..... 363
Anthrax, neosalvarsan in treatment of... 335

PAGE.

Anthropology of human eye..... 82
Antidote for arsenic, bismuth, and mercury poisoning 482
Antimony tartrate in schistosomiasis (Bilharzia disease) 229
Antiseptic, intestinal, use of perchlorides of mercury and iron as..... 363
Antitoxin, diphtheria, hemolytic and agglutinative properties of..... 51
Antrum, carcinoma of..... 414
Aortic regurgitation, life expectancy with. vasodilatation in, and capillary pulsation 574
Aortitis 533
syphilitic 574
Apfel, Harry. Hypertrophic pyloric stenosis in an infant 17
Appendicitis, acute, in children..... 625
Appendix, acutely inflamed, pathology of.. 360
Aristotle's views on the kidney.....28, 78
Aromatics 32
Arsenic poisoning, antidote for..... 482
Arsenical preparations in treatment of syphilis 126
Arsphenamine in cure of syphilis in rabbit. 304
Arteriosclerosis 574
and diabetes 470
and hyperpiesis 253
Artery, renal, aneurysm of..... 254
Articular rheumatism and malaria 575
Arthritis and focal infection..... 542
deformans, colloidal sulphur in....24, 75
gonorrheal, with purulent fluid in synovial space 428
in adult, with splenomegaly and leucopenia 575
Arthroplasty 306
Asphyxia of child during delivery, chloroform anesthesia in..... 521
Asthenia and syphilitic polyglandular disturbances 290
Asthma, prophylactic gas filtering ventilator for 164
Atomizer in nose and throat work..... 541
Automobiles, dangers of 342
Autopsies following carbon tetrachloride treatment 598

BAAR, Gustav. The Allgemeine Krankenhaus 242
Bacillus, foot and mouth disease..... 244
Back, pain in..... 149
Bacteria in urine of children and pyelitis.. 624
intestinal, production of formaldehyde by 360
invasion of uterus and its contents.... 519
Bacterins, value of..... 74
Bag, hydrostatic, in induction of labor... 415
Barker, Lewellys F. Social significance of medicine 53
Barnes, George Edward. Alum oil spray and Eustachian and nasopharyngeal vaporizing tubes 26
Barro Colorado Island Research Laboratory 36, 38
Bartle, Ira D. Excess blood sugar in connection with certain surgical conditions 207
Basedow's disease, extract of myxedematous goitre in treatment of..... 197
Bastedo, Walter A. Our northern chronic dysenteries 201
Bathing, history of..... 78
Beccari process of garbage disposal..... 132
Bel, George S. Aortitis..... 533
Bell, F. McKelvey. Aniline dyes in the treatment of infections 437
Bellevue Hospital, surgery in, fifty years ago 551
Benjamin, Harry. Influence of röntgen rays on endocrine glands..... 585
Benzoin, colloidal, reaction of in cerebrospinal fluid 304
Besser, Herman. (See supplement index.)
Biddle, A. Graham. Modern cataract operations 434
Bienfield, Henry H. (See supplement index.)
Bile changes caused by pressure obstacle to secretion 363
direct examination of, in gallbladder lesions 9, 60
in metabolism 362
total 363
Bilharzia, papillomatous, of rectum..... 361
antimony tartrate in treatment of..... 229
Biliary drainage, nonsurgical 69

BIOGRAPHIES:
Addison, Thomas 339
Aristotle 338

PAGE.

BIOGRAPHIES:
Brown-Séquard, Charles Edouard..... 30
Chervin, Nicolas 232
Graham, James 190
Hall, Granville Stanley 23
Hunter, John 129
Keats, John 284
Jenner, Edward 80
Laennec, René Théophile Hyacinthe 286
Lister, Lord 444
Marat, Jean Paul 180
Rush, Benjamin 393
Scharlieb, Mary 238
Schweitzer, Albert 606
Virchow, Rudolf 499
Wesley, John 180

Biologist, Aristotle as 338
Bishop, Louis Faugères. (See supplement index.)
Bismuth in treatment of syphilis....547, 600
poisoning, antidote for..... 482
Bland, P. Brooke. Radium therapy in gynecology 101, 156
Blauner, Samuel A. Interpretative value of the physical signs of the heart in acute rheumatic endocarditis in children.... 485
Blood cells, white, induced increase of, effects on infection 580
changes, chemical, after intestinal obstruction 360
chemistry, effect of ultraviolet light on.. 589
glycosis in, with relation to diabetes.... 307
plasma in infancy, significance of protein factions in 626
pressure, abnormalities of, associated with tinnitus aurium..... 574
allergic high, controlled by epinephrin 596
and methyl guanidine 237
and sugar metabolism 574
effect of methyl guanidine on..... 255
high 89, 565
and cerebral hemorrhage 566
osmotic pressure of blood pressure in pathogenesis of 254
in sleep and dreams, relation to hemorrhages, angina, and sudden death.. 253
relation of to amount of renal tissue.. 575
response to sodium nitrite, influence on water excretion 255
proteins, osmotic pressure of, in pathogenesis of edema and of high blood pressure 254
sedimentation 459
serum, calcium content of, effect of thyroidectomy upon 196
sugar and diabetes 470
and sugar in cerebrospinal fluid of the insane 412
content in diabetes.....200, 433
estimations omitted in insulin treatment of diabetes mellitus 307
excess, in certain surgical conditions.. 207
vascular system of extremities, diseases of 252
Boas, Ernst P. (See supplement index.)
Boas, Ernst P., and Livingston, W. H., Chronic diseases 153
Bone, giant cell tumor of 469
marrow, red, in treatment of anemia.... 281

BOOK REVIEWS:

surgery of 305
tumor 199
Pituitrin and physostigmine, action of.... 199
Placenta, adrenalin in manual delivery of 197
Plague, bubonic, treatment of..... 26
great, of London 502
Plasma, blood, in infancy, significance of protein fractions in 626
instability of, in sick infants..... 625
Platelet count in pernicious anemia, by Thomsen's method 468
Plication, fascia, for inguinal hernia..... 627
Pneumonia, early diagnosis of..... 49
treatment of 536
Pneumothorax, artificial, permanent results of 49
Pneumoventricle of the cerebrum..... 150
Poisoning, acute mercuric chloride, rationale of 427
alcoholic 353
botulinus, central nervous system in... 468
food 35
Poliomyelitis, acute anterior, early mechanical treatment of 150
Polyarthritis, treatment of with activated colloidal sulphur 24, 75
Polycythemia vera, clinical study of..... 319
Polyglandular disturbances, syphilitic, and asthenia 290
Polyuria and diabetes insipidus 98
Postmortem examination, first known in new world 447
Postoperative infection of upper abdomen 473
Postpartum paralysis, transient, of recurrent laryngeal nerve 468
Pregnancy and cancer, especially cancer of breast 414
and diabetes 455

PAGE.

Pregnancy, cardiopaths in 518
diagnostic applicability of phloridzin glycosuria in 521
glycosuria of, and socalled renal diabetes 520
late toxemias of, aftereffects..... 520
starvation toxicosis of 519
treatment of hydrops in 521
Proctology, abroad 490
Prophylaxis by external version; breech presentations 415
in coryza and asthma..... 164
serum, of measles 51
Protein fractions in blood plasma in infancy, significance of 626
reaction, nonspecific 387, 440, 495
Pruritus vulvæ, treatment of..... 229
Psychiatry, rapidity of sedimentation of erythrocytes in 412
relation of individual psychology to.... 412
Psychoanalysis, evolution of 235
Psychology, individual, in relation to psychiatry 412
Psychotherapy, growth of 235
Public health and modern novel..... 289
in New York 562
work and nuisance prevention..... 33
Puerperal sepsis, serum treatment of..... 496
Puerperium, paradoxic ischuria in..... 518
primary repair of perineum during.... 521
Pulsation, capillary, and nasodilatation in aortic regurgitation 574
Pyelitis and bacterial count of urine in children 624
in infancy and childhood, diagnosis and treatment 624
Pylorus, congenital stenosis of and Rammstedt-Weber operation 361
hypertrophic stenosis of 361

QUACKERY, conflict of with medicine 395
Quadriceps, separation of from patella 306
Quinine urea injection for sciatica..... 413

RABELAIS, fingers mentioned by..... 127
Rabies 142
Radiology, new journal of..... 506
Radium, closure of bronchial fistula by... 590
therapy in gynecology.....101, 156
of thyroid 198
Rahmet, H., Bey. Hydrophobia and carriers 591
Rammstedt-Weber operation for congenital pyloric stenosis 361
Rank, Otto. (See supplement index.)

LIST OF ILLUSTRATIONS TO VOLUME CXX

PAGE

Abdominal postoperative infection. Two illustrations 473–476
Addison, Thomas. One portrait 339
Ala deformities, operation for. Two illustrations 72–73
Allgemeine Krankenhaus. Two illustrations 242–244
Amsterdam Institute for Brain Investigation. One illustration 263
Angina pectoris, surgical treatment of. Three illustrations 311–314
Aortic regurgitation, life expectancy with. One chart 417–421
Barro Colorado Island Research Laboratory. Three illustrations 38–39
Auscultatory percussion and palpation. Eighteen illustrations 367–371
Bellevue Hospital fifty years ago. Nine illustrations 551–557
Bolk, Louis. One portrait 261
Brown-Séquard, Charles Edouard. One portrait. 31
de Boer, S. One portrait 261
de Kleijn, A. One portrait 261
Empyema, acute. Four illustrations 429–433
Esophagus, foreign bodies in. One illustration 168–170
Examination of bile. Forty illustrations. 9–13, 60–62
Face, congenital malformations of. Two illustrations of 5–8
Familial diseases of locomotion. One chart. 257–260
Gynecology, radium therapy in. Two illustrations 101–107
Hall, G. Stanley. One portrait 23
Hay fever. Two illustrations 4–5
Hernia, inguinal, operation for. Five illustrations 57–59

PAGE

Heterotopia of central nervous system. Fifteen illustrations 327–332, 385–386
Hippocratic nephritis. One illustration 230–232
Hunter, John. One portrait 130
Insulin dosage. Two charts 372–374
Janeway, Edward H. One portrait 553
Jelgersma, E. One portrait 261
Jenner, Edward. One portrait 81
Laennec. One portrait 287
Lister, Lord. One portrait 445
Magnus, R. One portrait 261
Maxillary sinus, diseases of. Two illustrations 582–584
Osteitis deformans. Two illustrations 62–64
Outdoor sleeping. Six illustrations 478–481
Phlebitis migrans. One illustration 64–68
Pyloric stenosis. Three illustrations 17–19
Rectal surgery abroad. Three illustrations. 490–493
Retractor for amputations of extremities. Three illustrations 171–172
Robinson, Andrew R. One portrait 240
Roman physician, unknown. One portrait 391
Sands, Henry M. One portrait 552
Sayre, Lewis A. One portrait 553
Stomach, primary sarcoma of. Four illustrations 161–164
Temple of Æsculapius at Cos. One illustration. 29
Tongue, foreign bodies in. Two illustrations 375–377
Transfusion apparatus. Two illustrations 171
Vaporizing tubes. One illustration 26–27
Uroscopy. One illustration 604–605
Wertheim Salomonson, J. K. A. One portrait. 260
Winkler, C. One portrait 261
Woods, James R. One portrait 552

INDEX TO SUPPLEMENT—VOLUME CXX

PAGE.

ABDOMEN, key to.....cvii
tumor of xxv
Abscess of lung, convalescent treatment of..xii
Adenoids in infants.....clxxviii
Adrenalinuria in relation to hyperglycemia...lix
Ahlswede, H. Edward, and Busch, Werner. Bismuth therapy of syphilis with oxybenzoic acid compound.....xcv
Age, old, harmfulness of caffeine and value of alcohol in.....clxiii
Aged, anesthesia in operations upon....clxxiii
nutrition of clxiv
Alcohol, value of, in old age.....clxii
Allergy as factor in idiopathic epilepsy...cxvii
Almour, Ralph. Conservation of hearing in suppurative middle ear diseases of childhood clxxviii
Amaurotic family idiocy.....cxxiii
Amster, J. Lewis. Local and regional anesthesia in operations on aged.....clxxiii
Anesthesia in operations on aged.....clxxiii
Angioma of larynx.....xiv
Appendectomy cvii
Appendix, disease of, simulating gastroduodenal ulceration xcvii
Appendoröntgenography in relation to surgical intervention cx
Arteriosclerosis, decrescent clxix
Auricular fibrillation, quinidine sulphate in lxxviii

BACTERIAL endocarditis, subacute, complicating pulmonary tuberculosis.....v
Beinfield, Henry H. Treatment of tonsillar hemorrhage xi
Besser, Herman. New technic for investigating maxillary sinuses by x rays.....x
Bishop, Louis Faugères. Mitral stenosis..lxxvii
Senile heart clxi
Bismuth therapy of syphilis with oxybenzoic acid compound xcv
Boas, Ernst P. Decrescent arteriosclerosis..clxix
Significance and consequences of hypertension lxxii
Bones, long, osteomyelitis in.....cxxxii
Boorstein, Samuel W. Fractures in region of elbow joint.....cxxxiv
Bradycardia lxv
Brahdy, M. Bernard. Preparation of lactic acid milk cxcii
Brain tumors, localization of.....cxxi
Bronchus, foreign body in.....xv
Brown, Sanger, 2nd. Psychopathic child..xlvi
Bush, A. D. Doses for children.....lxxxiv
Byrd, Hiram. Blocking off remote pain at nasal ganglia cxxvi

CAFFEINE, harmfulness of, in old age..clxiii
Cancer following luetic necrosis of frontal bone.....lxxxv
Cancer of colon xvii
of esophagus, metastasis from.....xix
of hepatic flexure of colon.....xxviii
of uterus, radium in treatment of....clxviii
Carcinoma of papilla of Vater.....ci
Carter, William Wesley. Adenoids in infancy, importance of early treatment..clxxvii
Cecopexy cvii
Cecoplication cvii
Chest, spinal metastases with latent primary focus in xx
Child, psychopathic xlvi
Children, conservation of hearing in....clxxviii
doses for clxxiv
goitre in clxxv
pyelitis in cxc
suppurative diseases of middle ear of..clxxviii
Colectomy cvii
Colon, cancer of.....xvii
hepatic flexure of cancer of.....xxviii
Complement fixation test in syphilis....lxxxvii
Confession, false xliii
Convalescent treatment of lung abscess....xii
Croup, differential diagnosis and treatment...vii
Cumston, Charles Greene. Progress of Italian syphilographers lxxxvi

DECRESCENT arteriosclerosis clxix
Deutschman, D. Prevention of perineal lacerations by episiotomy cl
Diet for aged clxiv
in causation of epilepsy cxv

Medical Journal and Record

A National Review of Medicine and Surgery, Established 1843

VOL. CXX, No. 1 NEW YORK, WEDNESDAY, JULY 2, 1924 WHOLE No. 2284

Medical Education

C. L. BONIFIELD, M.D.,
Cincinnati

In recent years there has been much talk and many pages have been printed upon the subject of education. Writers like Professor McAndrews, who has recently been called from New York to take charge of the Chicago schools, tell us at length and in detail of the many improvements that have been introduced into the methods of the public schools, while other writers are equally positive that our system of education does not educate, that after the student has gone through high school, a state university, or even one of the great colleges, he still is poorly prepared for his life work. Medical education has also attracted much attention and has undergone almost a revolutionary change since the beginning of the present century. Some of these changes have been necessary on account of the progress of medicine; others are due to the desire for a change and the fact that the medical profession has lost control of the education of those who would enter its ranks.

That it is the chief function of a medical college to prepare its students for what in the country districts is still called general practice is not doubted by many physicians. If one wishes to practise a specialty he should acquire the special knowledge and the special technical skill after receiving his degree and serving his year as an interne in the hospital. Two or three years in active practice in a rural community, where his services are now much needed, and where consultations are obtained with difficulty, would give him a still firmer foundation upon which to rest the knowledge of his chosen specialty.

But just how best to prepare the student for general practice is a question that is not yet settled. With the advent of the laboratory came the fulltime professor. No one would argue that his teaching is less important than that of the clinical teacher but on the other hand it must be recognized that many laboratory men have never graduated in medicine, and few of them have practised medicine for any length of time, if at all. Therefore, they have not the viewpoint of the doctor, the man who carries his knowledge to the bedside and applies it to the cure if possible of the sick, or if that be not possible to the relief of suffering. For this reason their teaching too often impresses the student as being a thing apart from the practice of their profession. This is a difficulty that at present there seems no way to remove. The best that can be done is to supply the deficiency during the last two years. It is therefore of the greatest importance that some of the teachers for the last two years be men who have practised medicine or surgery with the environment most of the students will have when they practise it.

Establishing and maintaining laboratories is expensive. "The laborer is worthy of his hire" and he must have equipment with which to labor. The fees of the students will not support a modern medical college. Therefore the colleges some years ago felt they must have endowment. If they had gone after it and secured it in a direct manner it would have been better for all concerned. But few men like to beg for money. It is especially distasteful to doctors. They would prefer to "let George do it." So instead of the medical colleges begging for money they knocked at the doors of the universities and asked for lodging. They were admitted and soon the universities found their new lodgers a heavy drain on the family purse and they begged for help. The help was to be had from the foundations if the universities would force their lodgers to do certain things. Figuratively speaking, they must all wear the same uniform like the bell boys of a hotel. The medical profession lost control of the education of those to come after. It sold its birthright for a pot of gold and it did not get the gold. Its guardians took charge of that.

The guardian and the donor concluded because the professor of mathematics or geology or Latin did not have any other occupation than teaching, the professor of therapeutics or of operative surgery should not have. Fulltime men for every chair was the goal ultimately to be reached. To have a doctor in actual practice teach anything was too much like the carpenter, the bricklayer, or the blacksmith teaching his apprentice.

The men in charge of the big foundations were not satisfied to make an experiment of fulltime men in the practical departments in one or two schools but have insisted that the experiment be a wholesale one and that every school that would receive their aid must promise sooner or later to use only fulltime men as heads of departments. The scheme has not worked as its originators anticipated. One of the reasons for its lack of success is that the leading

Copyright, 1924, by A. R. Elliott Publishing Company.

practitioners of medicine or surgery or the various specialties in a given community no longer take any real interest in the medical college. Another one is that the teachers are nearly always transplanted from one community to another and in the new environment they are not at home. They do not understand the currents and crosscurrents that always exist in the medical profession of a city and it takes them months and years to acquire this knowledge and learn how to use it for the benefit of the institution with which they are connected.

In former days the young men in a town where a college was situated felt that if they took a subordinate position and filled it satisfactorily they were in line for promotion. They had a chance some time to become a professor. The critics of the old regime claim that this was a bad thing because a man expected to be promoted on account of seniority in service as in the army, but this statement is not true. He knew perfectly well that there were others striving for the coveted position and that he must do better than they or it would never be his. This certainly was an incentive to the younger members of the profession to strive for recognition by the profession rather than strive for a large and lucrative practice. It therefore may be said that putting imported fulltime men into the positions of honor has a tendency still further to commercialize the practice of the healing art. Commercialism is the cancer that is destroying the vitals of medicine as a profession. The young man beginning his life work as a doctor now does not think of it as a work of service, but a work for the coin of the realm. He is not willing to begin at the bottom. He will not do charity for charity's sake. He may do it for a reward that is slightly deferred but not so deferred that it will be received in heaven. Ferrero, the Italian publicist, has pointed out the fact that the most obvious fault of Americans when compared with the nationals of an older culture is that they mistake bigness for greatness—quantity for quality. Our colleges, especially the state and municipal universities, seem to be victims of this delusion. The more students they have the bigger they are, therefore, in their own estimation, the greater. I know of one university that employs a publicity man. Is it surprising that a young doctor educated in this atmosphere measures his success by the number of patients he has rather than by the benefit they derive from his treatment?

Possibly the worst feature of the university advertising and the publicity seeking of the fulltime professor is that it is a wolf masquerading in sheep's clothing. The fulltime man professes the highest ideals but he doesn't live up to them. From the very nature of his position he enters into unfair competition with his competitors, all the time assuming an air of superiority and apparently feeling that the patient that falls under his care is so much better off than if she had gone to some other surgeon that it matters not how she is influenced to consult him. But I find out that they make just as many mistakes in diagnosis as the average surgeon.

This publicity craze is not only affecting the graduates of the present time but those who have been out longer seem to be inoculated with the same germ. The College of Surgeons was said to be organized to improve the quality of the surgery being done in this country and the ethics of those doing it. Yet at its recent meeting in Chicago its activities were so featured in the daily papers that one levelheaded doctor was led to remark: "If the American Medical Association is not able to handle the situation in such fashion that it will not arise in the future, our attitude toward the cults should be one of brotherly love and affection." *Harper's,* for February, contains a long article by a staff correspondent, evidently inspired by some one high in the councils of the college. The gist of this article may be stated in two short sentences—*"For the love of Mike" do not let any one operate on you if he cannot write F.A.C.S. after his name. Members of the college regard it as no sin to steal a patient from a surgeon who is not a member.* Every one who has given the matter any thought knows there are many good surgeons outside the college and many poor ones in it. We would humbly suggest the following lines as a part of the college song:

> "Count that day lost, whose low descending sun"
> Finds thee with no publicity secured,
> No advertising done.

It is asserted for the fulltime professor that he has acquired the art of teaching. To just what normal school he went I have never yet been told and have never been convinced that he is altogether a better teacher than the man of experience in practice. Let us consider for a minute what a teacher should do for his pupils. First, he should impart knowledge—it should be imparted in a way that interests the student and in a way that makes the students anxious to learn more about a given subject and it should be imparted in such a way as to give the student the proper perspective, that is, a proper emphasis should be placed upon the more important things, the things that the practitioner must know and must know he knows. As to the less important, he often has an opportunity to refresh his memory about. Who is best able to recognize these things, the man who practises in the well equipped hospital with a laboratory at his command and consultants at his beck and call, or the man who is seeing patients in their own homes and seeing them in consultation in rural communities where it is imperative that he make at least a tentative diagnosis after one examination of the patient. It seems to me the answer is selfevident.

A friend of mine was present at a quiz on diseases of children where the class had been trained by a fulltime professor. The disease under discussion was whooping cough. The students told everything to be known about the disease but failed to mention the whoop. More than one skillful practitioner has been called from his sleep at night because the baby had a cough and has made a diagnosis and saved himself a trip by hearing the baby cough by means of the telephone.

Another function of the teacher is to inspire the student. Who inspires the young man most? It is the mature man who occupies the position to which the young man hopes to attain. Youth makes a hero of a man who wins, let it be in the prize ring, on the football field, a political race, or any other place where a man struggles against competitors. The practitioner who has won his laurels in the open field appeals more to his imagination than one who lives a life sheltered by academic walls.

So anxious have colleges been to fill their chairs with fulltime men that they call men fulltime whether they are or not. They never take up a man who is engaged in active practice and pay him so much a year to devote so many hours to the college work but they do bring strange men, pay them for their work, and then let them devote part of their time to practice. Now this looks like tweedledum and tweedledee to me, but the learned authorities insist that there is a difference, but I have never had one tell me just what the difference is. In a medical college with which I am familiar the professor of medicine draws a salary, with the privilege of seeing cases in consultation; the professor of physiology draws a salary with the same privilege; the professor of pediatrics draws a salary with the same privilege; and the professor of surgery draws a salary with the same privilege and some perquisites besides, but the professor of surgery draws no salary, although he devotes as many hours to college and hospital teaching as either of the other gentlemen named. The professor of obstetrics is a man of great ability. He writes better on the mechanism of labor than any other author whose writings I have read, but he is not now paid and I presume as soon as the foundation will furnish a little more money this man who practises and teaches will be succeeded by a man who teaches and practises.

Along with the fulltime professor came the fulltime dean. Many of my readers will recall the opera of *Pinafore* and the little song in which the young naval officer is advised that if he would rise to a high rank in the service, he must be sure not to go to sea. Some of the universities in their selection of deans would seem to have acted on this principle instead of taking a man who had been teaching medical students for many years or a man who had a large consultation practice, and therefore knows what the young practitioner needs. They select a retired army or naval medical officer or some one whose actual contact with the working profession is equally meagre. Such a man can, in the seclusion of his office, draw a beautiful diagram showing how a medical college teaching corps should look on paper, but he is unable to draw a diagram that shows how best to utilize the material that he has at his disposal. He seems to forget that doctors are men as well as doctors. Most of them have their strong points and their weak points. Their strength must be used for the good of the institution, their weaknesses kept in the background. The president of the university not being a physician of course does not have a physician's viewpoint and is not familiar with the traditions of medicine. A dean of the type described is poorly equipped to enlighten him on these matters. The president of a university told a friend of mine recently that he didn't feel that a medical college was under any obligation to the teachers who had served the institution for years "without money and without price" because he felt that in some way they must have been paid for their services or they would not have rendered them. One would think such a man had never heard of the charity work done by almost every physician in public hospitals and in private practice, that he did not recognize that one may be fond of teaching for teaching's sake, and that the oath of Hippocrates, which has been followed in spirit by the medical profession for so many centuries, makes it incumbent upon a doctor to impart what he knows to those who are following him. He does not recognize the fact that as some men advance in years they like to continue to associate with the young. I have done nothing else in my career that I feel has made my life so worthwhile as having developed four young men to be good abdominal surgeons and gynecologists, but the thing that comes next in importance is the influence I have had on the medical students whom it has been my privilege to teach.

The fulltime man treating only charity patients does not have to please the patient to keep him under his care. Therefore he does not take the trouble to do those things which may seem trivial when considered singly but in the aggregate add much to the patient's comfort of body and mind and in so doing sometimes tips the trembling balance in which the issues of life and death are being weighed in favor of the former and saves a human life. Not using these measures he fails to appreciate their value and does not teach them. The fulltime man teaches about all there is to know concerning those serious diseases that are inevitably fatal in a rather large percentage of cases and the rarer the disease the more he is delighted to expatiate upon it, but those lesser ills that will furnish the young general practitioner with ninety per cent. of his work are ignored or receive very scant attention. It is true that time will cure many of these ills sooner or later but the patient does not know this and probably will not believe it if told. From his viewpoint a doctor that cannot do something to help in or hurry the cure is a poor excuse for a doctor. Receiving little attention and no benefit from the doctor he tries a representative of one of the cults, where he at least gets a sympathetic hearing. The doctor has lost a patient, the profession has lost caste. This patient tells his experience to a friend whose symptoms, to him, seem very similar to his own. Number two goes where number one is supposed to have been cured, but number two's symptoms are produced by an organic disease whose early treatment is of the utmost importance and the time for receiving this treatment is frittered away while he is under the care of one who is incapable of recognizing the true nature of the disease. Who is to blame for this death?

Matthew Arnold expressed the wish of many men and many women when he wrote:

> Nor bring to see me cease to live
> Some doctor full of phrase and fame
> To shake his sapient head and give
> The ill he cannot cure a name.

This is the way medicine is practised by the pure scientist. The true practice of medicine is an art as well as a science. The artist selects his therapeutic measures as a skilled workman selects the tools to use. He cures his patient when it is possible and when it is not he prolongs life, and makes living more worthwhile, and at the end gives him the blessing of euthanasia. Art can only be taught by an artist and artists are few in the ranks of fulltime men.

In my opinion the fulltime professor may fill a useful place in clinical teaching of medicine or surgery but the services of the man in active practice with a broad experience, with love for his fellowman, with ability to teach, are indispensable.

Comfort for Hay Fever Subjects at Home

WILLIAM SCHEPPEGRELL, A.M., M.D.,
New Orleans
President American Hay Fever Prevention Association, Chief Surgeon of Hay Fever Clinic, Charity Hospital.

Thousands of hay fever subjects make annual pilgrimages to hay fever resorts in order to escape the pollen infected atmosphere (Fig. 1) of their home surroundings. While this number has been materially reduced by the benefits of modern immunizing methods, the number is still exceedingly large.

In some cases, such a journey is considered a form of vacation, and causing no special hardship. In others, however, on account of impaired health, business or professional duties, or other reasons, such a trip is impracticable, or causes such a loss or inconvenience that any reasonable method of obtaining relief at home would be welcomed.

Hay fever subjects usually suffer more from their attack at night, and with a view of diminishing the number of inhaled pollen, many close the doors and windows of their room as far as possible. As most of the hay fever seasons occur during warm weather, such a method is not conducive to health or comfort.

An efficient method of making an apartment pollen proof is by means of an airwashing apparatus, made on the principle of those used with the modern heating and ventilating systems. While the expense of its installation precludes it from general use, it has special advantages for sanitariums, hotels and private residences in which the comfort of hay fever subjects justifies the expense.

The airwasher consists of three distinct parts (Fig. 2); the spray chamber, the eliminator plates, and the tank for catching the spray. Besides these, there is a recirculating group for supplying the water, and a screen or filter for removing the pollen and dirt from the water used in the spray chamber, as, for economy, the water is generally used over and over again, fresh water being replaced when required.

It is only from a rain of several hours' duration that thorough washing of the air results; consequently, when the air is passed through a spray chamber at a velocity of several hundred feet a minute, the length of time that it is in the chamber is exceedingly short, and the washing action of the spray is not as effective as nature's method, where the air is subjected to the washing action for hours at a time. Consequently, to obtain complete removal of dust, other devices are resorted to, and in this case the eliminators produce the desired result in both washing and eliminating.

FIG. 1.—Photomicrograph of atmospheric pollen plate, showing infestation of air with grass and ragweed pollen. × 200 diameters.

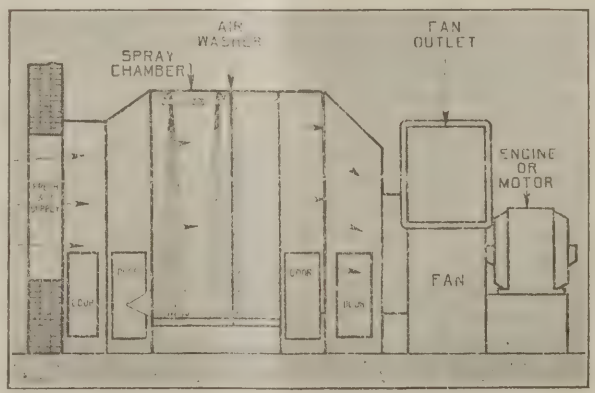

FIG. 2.—Airwashing system for hay fever pollens.

Due to the zigzag passageways, the air first strikes one surface and then another of the plates. As considerable moisture drifts along in the air, these plates become wet, and the surplus water is flowing over them all the time to the sump below. Due to the impinging action of the air on the plates, the dust and pollen particles adhere to the wet surface, and are washed into the sump. To make this action more positive, it is customary to provide nozzles adjacent to the eliminators, to keep them thoroughly washed down.

Eliminators form an important part in the air washer. The function of these is to remove the entrained water carried over by the air from the spray chamber before the air leaves the air washer. The eliminators are so designed that the air must change its direction several times and pass over the sharp edges of the metal sheets.

The sump is made of sheet metal, and is provided with a strainer and overflow, and the height of the water within it is maintained at a constant level by an automatic valve. It encloses the lower part of the spray chambers and the eliminators. A centrifugal pump drains the water from the sump through a strainer and recirculates it through the spray nozzles so that it can be used again.

The ventilation of the apartments protected from pollen by the airwasher, is accomplished by means of a centrifugal fan. This consists of a number of blades extending radially from a shaft, and presenting a slightly inclined surface to the air as they revolve. The air is drawn axially at the centre, and delivered from the tip of the blades in a tangential direction.

The fan forces the air through the airwasher into the apartments, and furnishes a continuous supply of air. The doors and windows are closed, so that there is no opportunity for pollen infected air to be drawn into the room from external sources, since the air is admitted only through the airwashing chamber. The fan maintains a slight pressure within the ventilated apartments, so that the tendency of the air is to flow outward and not inward. The escape of the air from the room is accomplished through the walls, cracks, spaces around the doors and windows, or through especially constructed vent flues such as are used in schools and theatres.

While the expense of this system prevents it from being adapted to smaller residences, a simplified form could be arranged which should add materially to the comfort of hay fever subjects.

MAISON BLANCHE ANNEX BUILDING.

Congenital Malformations of the Face

REINHOLD F. HERTZBERG, A.B.,
and G. R. R. HERTZBERG, M.D., F.A.C.S.,
Stamford, Conn.

Every species of animal has a type form. In man, particularly, we learn to recognize this standard pattern, within whose limits wide individual variations may occur without exciting either astonishment or curiosity. Especially is this true of the face, since, under ordinary circumstances, this is the most exposed part of our anatomy. Occasionally, an unfortunate person is born, who, through some abnormality of intrauterine development, presents a departure from this normal mold—is atypical. Such a condition is called a congenital malformation. When this malformation is of an extreme or greatly exaggerated variety, the resulting entity, whether alive or dead, composed of single, double, or multiple persons, is spoken of as a monster or teratism. The study of such monstrosities is known as teratology. The subject is an extremely broad one, and in a paper of this sort, even though limitation to the discussion of malformations of the face alone is sharply made, one can only hope to scratch the surface and give a superficial survey of the many atypical configurations which arise, and a brief presentation of the questions and speculations which they involve.

Ziegler divides etiological factors into two groups, the intrinsic and the extrinsic. Under the first he includes such malformations as are due to defects in the germ plasm, those which can be traced to an hereditary origin. Just how important is the rôle which heredity plays is an open question. Ochsner reports that there was only a small percentage of cases, approximately ten per cent., in which it could be determined that blood relations were similarly affected. In the Southern States, where family histories are more readily ascertained and where consanguinity might also be expected to reveal defective determinants, because of the frequent intermarriage of more or less directly related persons, heredity appears to be influential much more frequently than among children born in the Northern and Western States. This is particularly true of such abnormalities as harelip and cleft palate.

Usually, malformations may be referred to extrinsic causes, forces working upon the embryonic organism from without, resulting in inhibitions of development, failure of paired anlagen to unite, or exaggeration and hypertrophy of the tissues involved. Extrinsic factors may be divided into three groups, mechanical, metabolic and toxic. A monstrosity may be produced by one or all three of these types of injury.

The best example of mechanical variety of trauma is that produced by the entanglement of the fetus in the umbilical cord. A leg, arm or neck may become encircled and the parts distal to the heart atrophy or become necrotic. Concussions of the uterus may result in irreparable damage to the embryo if coming at a very early age. Later on in fetal life, trauma of this sort is more likely to result in a tearing loose of the developing person, resulting in local hemorrhage and disturbances in the placental circulation and thereby in the nourishment of the new organism. Pressure from the uterus or its membranes may be exerted upon the embryo, particularly when the amount of amniotic fluid is deficient. There may be an excessive amount of amniotic fluid which results in malformations due to pressure atrophy. Adhesions may occur between the embryo and its membranes; to what extent these are to be referred to "primary adherence and intergrowth and to what extent to inflammatory processes of later occurrence, is yet a disputed question." All that shows at birth, disregarding the more frightful monstrosities, is often just a cicatricial area. Of course, many varieties of mechanical lesions occur, but upon careful inspection the cause of the malformation is usually detectable.

Disorders of metabolism undoubtedly play a more important rôle than is usually assigned to them. Interference with the supply of oxygen and nourishment has already been alluded to as being secondary to mechanical injuries of various sorts. In the finely balanced chemical forces of the endocrine system, there are infinite possibilities for the disturbance

of factors controlling growth and development. The system itself has practically sovereign control over metabolic changes, as is evidenced by diseases of, and animal experimentation upon, the thyroid, thymus, epiphysis, testes, ovaries, hypophysis and so forth. If endocrine disorders can have such a profound effect upon the adult being, how much greater and more powerfully must they affect the embryonic organism.

Toxins of bacterial or maternal origin have their deleterious effects. Contaminations of the maternal blood, as in the infections and pathological conditions of the uterus, may exert a harmful influence upon the developing ovum. Psychic states of the mother undoubtedly result in leaving a stamp, either mental or physical, upon the child. Infectious diseases like syphilis may be transmitted through the placental circulation, and give rise to their characteristic lesions in the fetus. The earlier the damage occurs, the greater the extent of the injury.

It must be borne in mind, however, that, even though the incidence of these traumatic forces is far from rare, all these conditions lead more often to the death of the fetus and the expulsion of the embryo, than to the development of a malformation.

As to the actual effects of these injurious conditions, aside from the destructive histological and organic charges, most malformations can be traced to inhibited or arrested development during early embryonic life. This is especially true of phenomena like cleft palate and harelip in which the nasal and palatal processes fail to fuse as is normal. For a better understanding, therefore, of malformations, it is well to take a hasty glance at the embryology of the facial region.

It will be recalled that the face arises from one single and two paired anlagen. The frontonasal process, which, roughly speaking, goes to form the forehead and the nose, comes down from above, while below, on either side, are the maxillary and mandibular processes which arose from the division of the first branchial arch. Thus, about five weeks after conception, the primitive buccal cavity, formed by the bending forward of the cerebral vesicle over the end of the notochord, has a quinqueradiate appearance. The mandibular processes unite early across the midline to form the lower jaw. Next, the medial nasal process, elaborated by the frontonasal process, unites below with the lateral nasal process of the maxillary process, thus forming the anlagen of the external nares. The fusion takes place from within outwards and occurs as the processes meet, so that the primitive nasal cavities are never connected with the stomatodeum, or primitive mouth cavity. Later, the bucconasal membrane breaks through and the posterior nares are formed. An area on the frontonasal process is soon delineated, the area triangularis, which forms the tip and dorsum of the nose. The median nasal processes, mentioned above, are pushed close together and finally unite to form the septum of the nose. The maxillary processes send out palatal plates, which unite with each other in the midline about the eighth week of fetal life and at the same time blend with the lower border of the nasal septum. The anterior portions of these palatal plates unite before the posterior parts. Failure of fusion of these palatal plates results in a cleft palate, which leaves the buccal and nasal cavities continuous with each other in the midline, instead of merely at the posterior nares.

In the formation of the nasal skeleton, it is the swellings of the mucous membrane, in which the turbinates later develop, that are the important structures—the bone is the negative tissue. It is thought by many that the conchæ grow out from the septum of the nose, and attach themselves to the lateral wall, later losing their connections with the medial wall of the nose. The external nares are closed for a time by epithelial growths, formed at first from the median walls. They plug the nares and project from them, not being absorbed until about the fourth month. These may persist for quite some time, however, and have even been known to occur in the newborn.

The external ear is formed by the union of six swellings from the tissue adjoining the first branchial groove, three on the mandibular and three on the hyoid arch. These go to make up the tragus, helix, antihelix and antitragus. Back of these an auricular fold forms which unites with a similar fold just dorsal to the first branchial groove, to form the outer part of the pinna; the point of union of these two folds often marks the position of the satyr tubercle. Darwin's tubercle appears at about the middle of the free margin of the auricular fold and corresponds to the apex of the auricle in lower animals. In some people these areas are quite conspicuous, the person having pointed ears.

The commonest malformations are those having to do with the upper lip and the palate, as one must conclude after a moment's recollection of the embryology of these structures. If the maxillary processes fail to unite, harelip results. If the palatal plates do not meet in the midline, the individual is born with a cleft palate. The point of fusion of the maxillary and frontal processes may be marked by a cleft or just a scar running from the mouth to the eye. And so there may be many variations according to the amount of fusion of the various parts.

Malformations of the lips and cheeks are usually associated with defective bone development, although harelip may exist without the phenomenon of cleft palate; or the lip may be normal and the cleft be present. The degree of injury varies and may be unilateral or bilateral. A fissure of the first degree is one in which only a portion of the lip is involved; one of the second degree, where the cleft includes the entire length of the lip from the prolabium to the nose; while the third degree includes wide fissures extending completely through the lip and alveolar and palatal bony structures. These fissures may extend even up to the orbits and are sometimes associated with other startling deformities, such as cyclopia, or median eye. In the case of bilateral fissures of the third degree, the premaxillæ may protrude, and unless immediate surgical procedure is taken or a strip of adhesive tape is fastened across the upper lip, the deformity may grow rapidly worse after birth.

The usual cleft is between the maxilla and pre-

maxilla. Median lip and palate clefts, less common, are of two forms: there may be a simple cleft in the midline or the premaxillæ and nasal septum may be lacking, causing a flattening of the bridge of the nose and a broad median defect, flanked by the maxillary portions of the upper lip.

Oblique facial cleft is rather rare and may extend from the usual situation for harelip below, along the line of the nasal duct, to the inner canthus. It may be limited to the soft parts, showing sometimes only as a cicatrix (the most difficult to repair with good cosmetic effect), or it may also involve the bones, even laying open the antrum. Congenital facial scars, often associated with a cleft uvula, may be all that remains as witness of retarded embryonic development.

Fissures of the mandible are rather rare. There may be merely a lip defect in the median line or the chin may be cleft. Sometimes the lower jaw is entirely wanting, a condition known as agnathia. In this case, the ears are usually large, low down, and often touching in the midline below —synotia. Sometimes the face remains in its early condition of a large cleft, the mouth, nose and possibly the eyes, united in the same cavity. The maxilla may be abnormally small, or the mandible greatly developed, either condition resulting in a prognathous lower jaw. The deformity may be the other way round, and results in socalled "chinless wonders."

Occasionally the mouth is malformed. The lips may be fused together or else the oral opening may be small—microstomia—and may extend backwards as far as the ears. With this in mind, a congenital scar arising from the corner of the mouth and running backward almost to the tragus should excite no surprise.

Deformities of the auricles are usually unilateral, rarely bilateral, except for the pointed ears mentioned previously. Complete absence of the auricles is not frequent. The helix, antihelix or tragus may be defective or the whole structure stunted—microtia. Macrotia, an exceedingly large pinna, is fairly common. Once in a while supernumerary auricles occur, a condition of polyotia; these are unilateral and more or less perfect, and are preauricular in site, as a rule, although occasionally they occur on the neck, cheek or shoulder. Little tumors of fibrous tissue, covered with skin and having a core of cartilage, fibrochondromata, sometimes occur in front of the ear and are believed to be elaborated from the tissue of the branchial arches.

Fig. 1.—Congenital absence of nose and eyes.

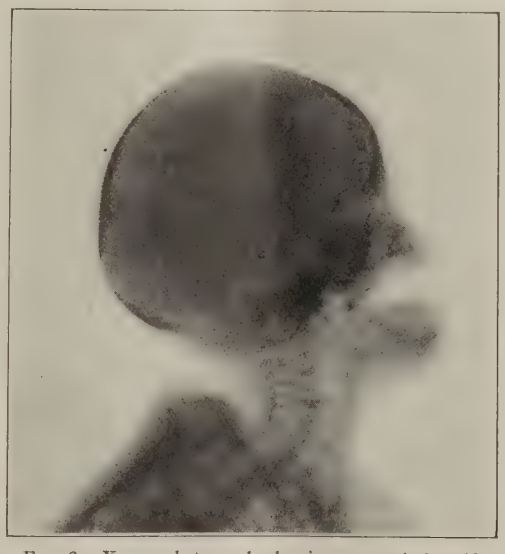

Fig. 2.—X ray photograph showing congenital malformation of face.

Rarely, the tongue may be entirely absent, or it may be cleft like a snake's, or half of it may be wanting or atrophied. When we speak of a person as being tonguetied, we mean that the frenum is usually short, fastening the tip to the floor of the mouth. This defect should always be sought in the newborn, and, if present, the tongue raised and the frenum, thus put on the stretch, cut across its centre with a blunt pointed scissors directed downwards. Sometimes the tongue is anchored to the floor of the mouth by folds of mucous membrane, a condition of ankyloglossia; it may be readily freed. Occasionally the tongue and its frenum are too long, permitting great mobility, and fatalities are on record from strangulation due to the swallowing of such an organ. Finally, a condition of great hypertrophy, known as macroglossia, may occur. This is due to a great increase in the connective tissue, secondary to lymphatic obstruction and dilatation. It is enlarged in all directions, protrudes from the mouth and is indented by the teeth, which interfere with the venous return, causing it to become purple in color. The mucous membrane becomes dry from exposure and assumes the appearance of skin, although saliva dribbles freely from beneath it.

Allusion has already been made to clefts and scars of the lips due to arrested development. One or both lips have also been known to be absent. A condition of macrocheilia, analogous to macroglossia, due to lymphatic obstruction, is fairly common. It usually affects the lower lip, causing great thickening and eversion, resulting in considerable deformity. The usual variety of this, however, is of luetic rather than of congenital origin.

When there is a third degree cleft of the palate, the nose and its septum are usually stunted or mal-

formed. Occasionally, the nose is completely lacking. Spurs and deviations of the septum are of frequent occurrence, as we all know. Sometimes the dorsum of the nose fails to rise and the nostrils appeal as blowholes at the base of the flat area triangularis.

Glaring deformities of the nose, whether of mechanical or toxic origin, are often accompanied by ocular malformations. In cyclopia, or single median eye, the nose is often displaced and appears as a tag of skin and fibrous tissue fastened to the forehead above the eye. The eyes may be only abnormally close together, or may occupy the same cavity, both structures being present. This is commoner than the presence of a single eye. Sometimes the lids are still fused together over optic structures which have failed to advance beyond their embryonic condition.

Congenital cerebral herniæ, in which the meninges, often accompanied by nervous tissue, occur in conjunction with cranial bone defects, and may appear about the eyes or forehead. A discussion of these is not within the scope of this paper, but they are mentioned here because they are among the commoner congenital defects.

Cases of giant growth or hypertrophy of one side of the face only have been recorded. Usually, however, the gigantism is unilateral for the whole body.

We come now to the more horrible of congenital malformations—those composed of two individuals—double monsters, socalled. All of them arise from a single ovum and develop from the same germinal vesicle. The development may be upset during segmentation, division of the twins being incomplete, or two entirely separated anlage may grow together again to form the dual teratism.

The simplest form of this malformation is that called a teratoma, in which the unfortunate twin occurs, usually in the mandible, as a sort of tumor, which, when opened, shows a great jumbling of a variety of tissues. The morphology of the tumor presents no semblance of human form.

It often happens that one of the twins has its development arrested and becomes joined to the other as a part of it. The more completely developed of the two is called the autosite, while the inhibited embryonic organism is termed the parasite. The latter may be variously developed, having divers organs, tissues, possibly extremities, and be almost as large as the autosite. When an acardiac individual of this sort is attached in the neighborhood of the jaw it is called an epignathus.

The heads of the twins may be united in the cranial, frontal or lateral regions, in which event the monstrosity is called a craniopagus, or, if the union is very intimate, a syncephalus. The faces may be equally or unequally developed and point the same way or in opposite directions. So many variations occur that classification is practically impossible.

In conclusion, a brief description of an interesting and unique anomaly will not be amiss, even though the subject of this thesis is not adhered to with rigidity.

On December 5, 1923, a female child, noseless and eyeless, was born. The delivery was perfectly normal, left occiput anterior, after a normal, full term pregnancy. The family history, so far as could be ascertained, was negative. The mother has always enjoyed the best of health and had had two previous confinements, resulting each time in the birth of a normal child; the first one was born on September 26, 1919, the second on August 17, 1921. Examination of the mother found her to be physically sound and to have normal pelvic measurements and no pelvic tumors. Upon the death of the child, it was impossible to obtain the body for autopsy, but photographs were taken and röntgenographs were used to supplement the physical examination.

The most striking thing about this monstrosity was the total absence of a nose. The eyelids were fused together over eyes which were felt to be rudimentary. The hard palate lay beneath the orbits, and the mouth, through which the individual respired, was constantly agape. The palatal plates, arched slightly more than is usually the case, had formed, and were fastened together in the midline by a plainly visible suture of fibrous tissue. There was a flat area of bone, covered with skin and superficial fascia, where the nose should have been. Evidently the growth of the nasal portion of the frontonasal process had been inhibited, and the maxillary processes had united and filled the space usually allotted to the nose. The skull showed no fontanelles nor suture lines, indicating a toxic etiology. Two pairs of branchial fibrochondromata were present, one set preauricular in position, the other attached to the skin above the sternoclavicular junctions. The mucous membranes of the anus and vagina were confluent, resulting in a cloaca such as birds and elasmobranchs possess. The teratism, aside from the malformations enumerated above, had a normal anatomical structure; the cranium was nicely shaped and the ribs, bones of the extremities, heart, lungs, stomach, kidneys, and intestines were, so far as could be discovered, without defects.

At birth, the monstrosity weighed three and half pounds and was in good physical condition. The mother refused to have anything to do with the child, which was therefore fed artificially. It experienced great difficulty in taking nourishment, since it had to stop and gasp for breath after every swallow. Six days after birth, on December 11th, it had gained one ounce, but lost this again by December 14th. It then began to lose weight steadily, until on December 18th it weighed three pounds and two ounces. Every effort was made to feed the child, but it became more and more difficult to nourish it. Finally on December 20, it died from inanition due to its inability to take sufficient nourishment.

In looking over the literature on congenital malformations of the face, it is surprising to find that the subject is not entirely a gruesome one. Remarkable results have been obtained with unfortunate persons, who, at first glance, seemed to be beyond repair. Some wonderful work has been done, and still remains to be done, in this field. With those individuals who live, good results are ordinarily obtainable, while those with the more marked malformations usually die in a short time after birth.

40 South Street.

A bibliography will be included in the author's reprints.

The Importance of the Direct Examination of Bile in the Diagnosis of Gallbladder Lesions*

MAX EINHORN, M.D.,
New York

In some instances gallbladder lesions[1] run a typical course and can then be easily recognized. Often, however, the symptoms are far from characteristic and a correct diagnosis becomes difficult; therefore everything that tends to increase our diagnostic methods is of value. X ray examinations have come to be more and more employed in this field of medicine and the findings obtained by this means are at times of considerable import. Thus, if a distinct shadow representing a calculus or calculi is discovered in the gallbladder region, a diagnosis of cholelithiasis can frequently be made. In

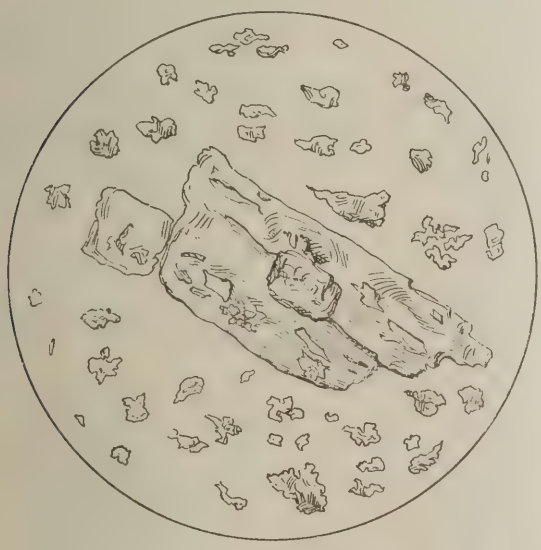

Fig. 9.—Mr. J. G. R. March 30, 1921. Bile yellow brown, very turbid; microscopically: very big and medium sized cholesterin crystals found (not operated).

addition to this direct x ray sign, there are a few indirect features pointing toward gallbladder lesion. First, sometimes after a barium meal an indentation or concavity in the duodenal cap may be found, which usually indicates the pressure point of the gallbladder over this region. Again, a dragging away of the pylorus—the first portion of the duodenum—further to the right, is probably caused by adhesions between the gallbladder and the duodenum. Defects or constant deformities of the cap may be due either to ulcerative lesions of the duodenum or to adhesions between the gallbladder and this organ.

The latest aid for obtaining a diagnosis in this field is the direct examination of the bile.

Bile is a product of the liver. When obtained from the duodenum in the fasting condition of the patient, it represents the secretion or excretion of the liver with some admixture coming from the bile ducts and gallbladder, and the pancreatic and duodenal secretions. As in the case of the urine, which no physician fails to examine in affections of the kidney, the bile should be investigated in all diseases of the liver, gallbladder, and pancreas, for it is often of the greatest assistance. In order to be of use, however, the examination should be performed with great caution.

First, the duodenal tube must be in perfect condition, clean and aseptic; the specimen of bile obtained must be subjected to examination while fresh—within half an hour or so after securing it. Normal bile, obtained in the fasting condition of the patient, is golden yellow and clear; while a pathological bile is always more or less turbid and subject to manifold variations in color. A yellow greenish peasoup appearance is a frequent occurrence in the severer affections of the gallbladder. The reason for the necessity of examining the bile very soon after obtaining it, is that it changes in color and also in character with the lapse of time.

After having observed the bile with regard to its appearance, and also after having determined its chemical character with regard to its alkalinity, a microscopic examination is made.

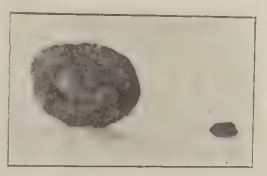

Fig. 10.—J. A. G. Duodenal ulcer and severe cholecystitis. Stone found in cystic duct at operation on October 30, 1922. The small particle to the right shows one of the many concretions which emptied from the common duct. One half times natural size. (New York Medical Journal, June 6, 1923.) The bile was turbid, containing pus corpuscles and calcium bilirubin crystals. In the duodenal contents, which were turbid, a blackish looking particle of pinhead size was found, which upon microscopic examination proved to consist principally of debris and calcium bilirubin crystals. Dr. Willy Meyer operated upon the patient. The gallbladder was not adherent, and to outward appearance it was almost normal. On palpating it the surgeon at first had difficulty in discovering anything wrong, but on further search a concretion was detected in the cystic duct, and on removing the gallbladder a solitary black stone was found in the cystic duct, while many small concretions were discovered, when the common duct was incised. When the gallbladder was opened the bile was dark and putrid.

Whenever a sediment is present, this must be separately examined. If there is no sediment, and the bile is simply turbid, after centrifuging the specimen the lowest layer may be selected for another examination. While the discovery of a few tiny cholesterin crystals here and there in the microscopic field is of no consequence, these crystals, if present in large numbers, are of significance. Occasionally pus corpuscles and bacteria are found. If the latter are present in great numbers, almost forming colonies, it is an important finding. Mucus is frequently observed. Occasionally the microscopic examination shows conglom-

*Read before the Newark Academy of Medicine, February 13, 1924, and before the Greater New York Medical Society, on April 21, 1924.

[1]In this article I take pleasure in publishing additional pictures with regard to the findings of the direct examination of the bile. Figures 1, 2, and 3, were printed in the New York Medical Journal, July 3, 1920, and Figures 4, 5, 6, 7, and 8 in the Medical Record December 10, 1921. For this reason I begin here with Figure 9.

Figures 9 to 25 are more or less characteristic for gallstones. The large size cholesterin crystals especially when lying in conglomerations (one on top of the other) are important evidences of biliary calculi. They are, however, not positive proof of the presence of a calculus. As was mentioned in one of my former papers they can occur but rarely without the presence of a stone.

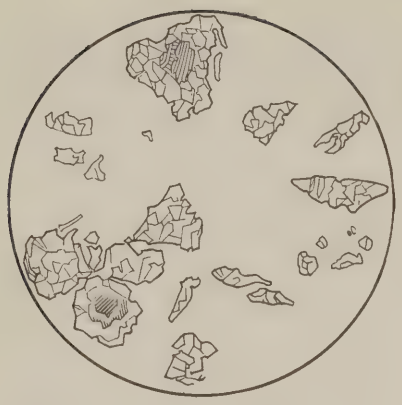

FIG. 11.—Mrs. J. F. February 19, 1923. Bile, dark brown yellow, very turbid, containing many cholesterin crystals. At operation gallbladder found filled with stones.

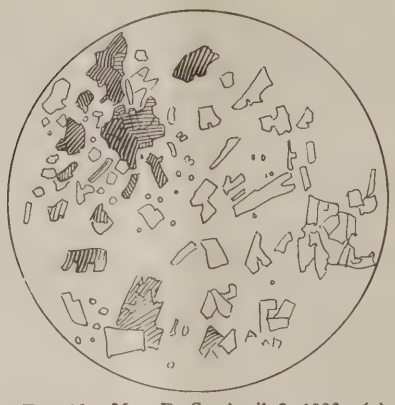

FIG. 12.—Mrs. D. S. April 2, 1923. (*a*) Bile obtained at operation very dark, almost black and turbid. Microscopically, big cholesterin and biliary salt crystals.

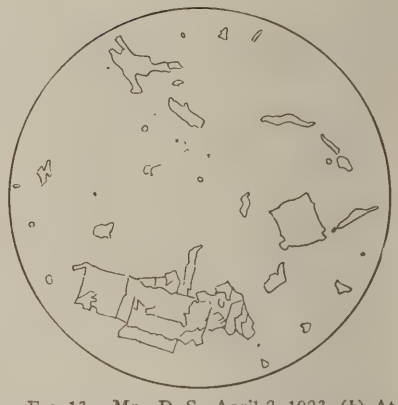

FIG. 13.—Mrs. D. S. April 2, 1923. (*b*) At the operation numerous calculi were found in the gallbladder. Numerous cholesterin crystals, similar in structure to (*a*).

FIG. 14.—Mrs. D. S. April 2, 1923. (*c*) Another scraping showed cholesterin crystals of very similar type as (*a*) and (*b*).

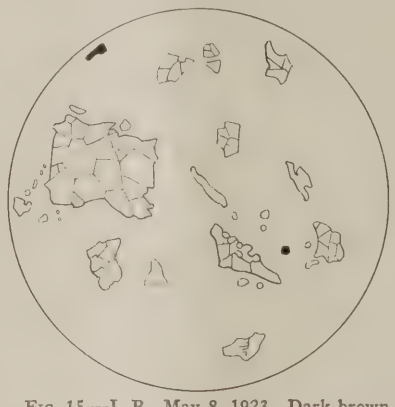

FIG. 15.—I. B. May 8, 1923. Dark brown yellow, very turbid. (*a*) Many cholesterin crystals; some in conglomerations.

FIG. 16.—I. B. May 8, 1923. (*b*) Mucus; peculiar crystals with concentric rings resembling spangolite crystals.

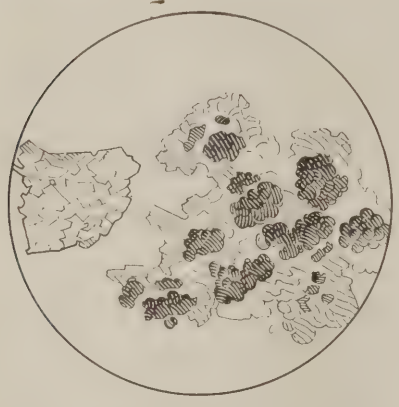

FIG. 17.—R. P. T. April 3, 1923. Bile, dark yellow, very turbid. Microscopically: mucus; cholesterin crystals; calcium bilirubin crystals.

FIG. 18.—Mr. H. R. April 25, 1923. Bile dark greenish yellow, very turbid. Microscopically: (*a*) many cholesterin and biliary salt crystals.

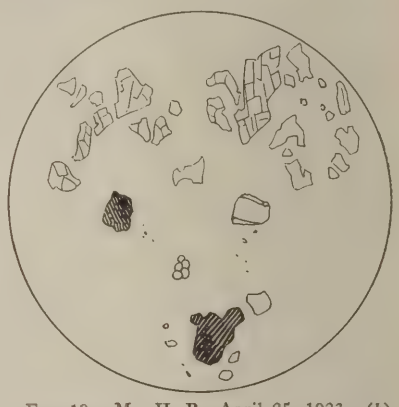

FIG. 19.—Mr. H. R. April 25, 1923. (*b*) conglomeration of cholesterin crystals; a few biliary salt crystals, mucus and pus corpuscles.

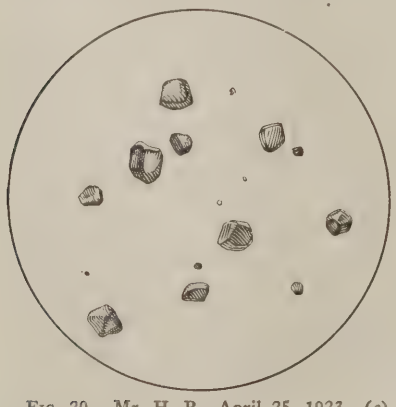

FIG. 20.—Mr. H. R. April 25, 1923. (*c*) Calcium bilirubin crystals.

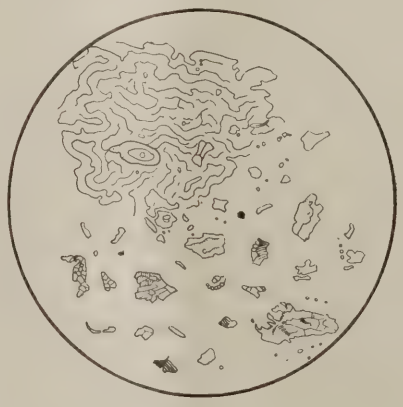

FIG. 21.—E. S. May 29, 1923. Bile, light yellow, very turbid.

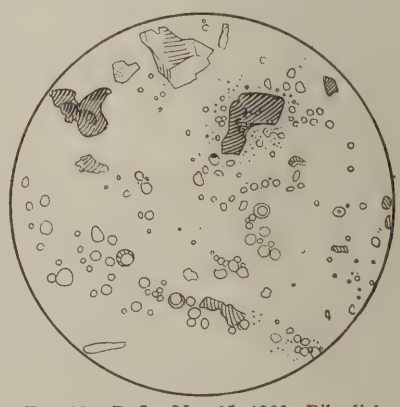

FIG. 22.—R. L. May 15, 1923. Bile, light yellow, brown and reddish tinge, very turbid.

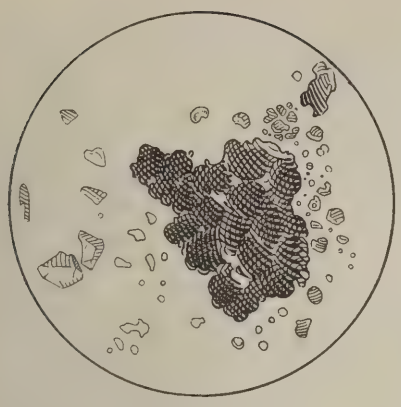

FIG. 23.—R. L. E. May 15, 1923. (*b*) Cholesterin and calcium bilirubin crystals. Patient not operated.

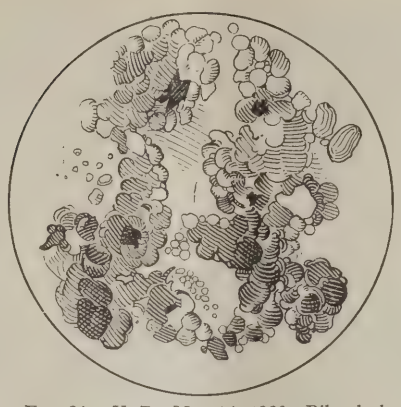

FIG. 24.—Y. R. May 15, 1923. Bile, dark yellow, turbid; mucus; calcium bilirubin crystals; pus corpuscles. Patient not operated.

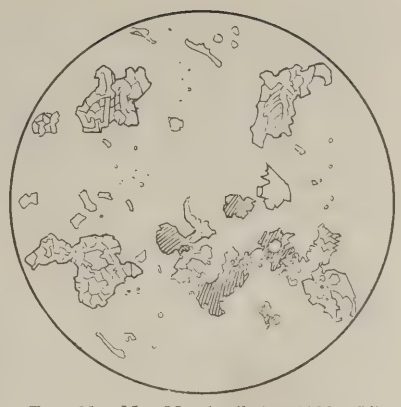

FIG. 25.—Mr. M. April 10, 1923. Bile, greenish yellow, very turbid. Mucus; pus cells; cholesterin crystals in conglomerations.

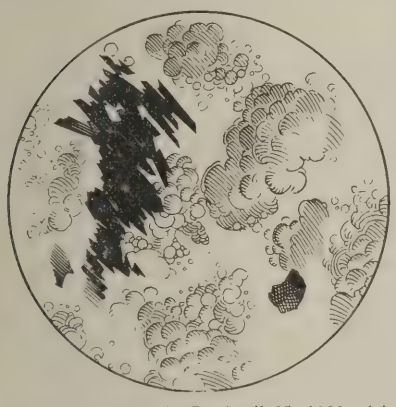

FIG. 26.—Mrs. A. S. April 25, 1923. (*a*) Bile, yellow green, turbid, small pinhead size particles, black.

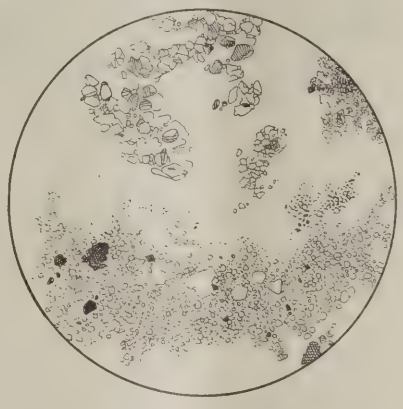

FIG. 27.—Mrs. A. S. November 9, 1923. (*b*) Bile dark brown yellow, clear. Blackish pinhead size particles.

FIG. 28.—Mrs. B. September 27, 1923. (*a*) Bile, dark yellow, greenish, very turbid; small sand like particles found.

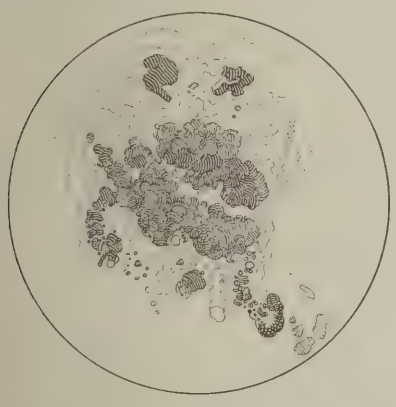

FIG. 29.—Mrs. B. October 3, 1923. (*b*) Black sandlike particles found in the opened gallbladder.

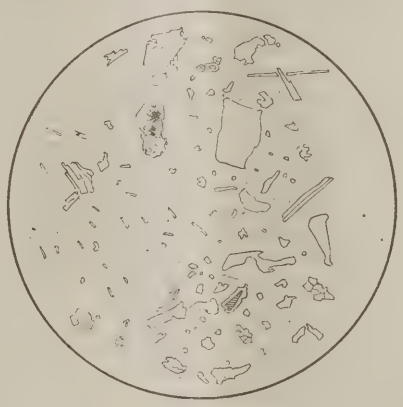

FIG. 31.—B. D. D. September 4, 1923. Bile light green yellow, turbid. Cholesterin and calcium bilirubin crystals and mucus.

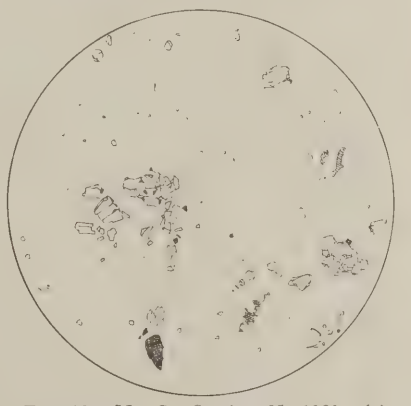

FIG. 32.—Mr. S. October 25, 1923. (*a*) Black sandlike particles found in the bile; cholesterin crystals and mucus.

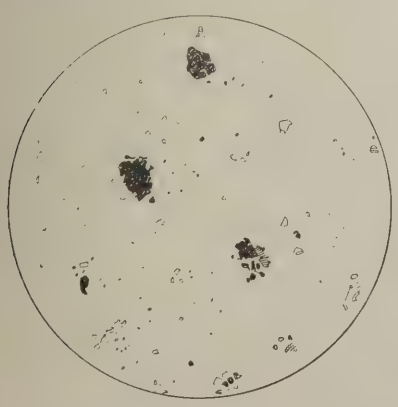

FIG. 33.—Mr. S. October 25, 1923. (*b*) Small cholesterin and black rhomboid crystals of various sizes (iron?).

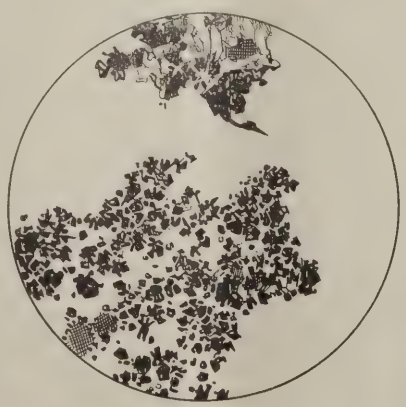

FIG. 34.—Mrs. R.—December 12, 1923. Pinhead size concretions: consisting of microscopically blackish looking crystals.

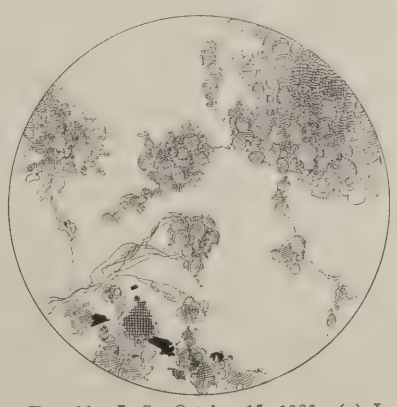

FIG. 35.—J. S. October 15, 1923. (*a*) In the bile tiny blackish concretions of pinhead size.

erations of large cholesterin crystals lying one on top of the other, which is suggestive of calculi.

In a number of instances the bile is either slightly turbid or clear or again very turbid and contains blackish or brownish or sometimes reddish particles of poppyseed size, or even smaller. These sandlike particles are at times very hard, at other times of a soft consistency. They are occasionally embedded in mucus, and at time float freely in the bile. When examined microscopically these particles are found to consist frequently of conglomerations of crystals: "bunch berry" variety, roundish crystals of bunch berry size, with a dark amber color; small black crystals of rhomboid shape, calcium bilirubin and small cholesterin crystals and a variety of other substances found in bile; bile salts and amorphous material. While these sandlike particles do not always indicate stones, they are always, I believe, signs of a pathological condition in the gallbladder.

Fig. 30.—Gallbladder of Mrs. B. October 3, 1923. (c) Outwardly no appearance of disease, but mucosa very much thickened and indurated, as though there were papillae. Three places of small ulcers(?). Black sandlike particles were found on the mucosa. The bile from the gallbladder after the operation looked dark, almost black, and contained many bacteria, cholesterin and calcium bilirubin crystals.

Some years ago Dr. Meyer and I (1) laid stress upon the necessity of a cholecystectomy even when no calculi could be palpated at a laparotomy, provided the symptoms and the previous bile examination evidenced distinct pathological findings. In a considerable number of these cases the sandlike particles mentioned are found in the bile. The following cases will illuminate this statement.

Case I.—Mrs. A. S. had been complaining of occasional migraine for a few months, and more recently of nausea accompanied by vomiting and pains in the gastric region. A detailed examination revealed the presence of an ulcer in the stomach, not far distant from the pylorus. A course of duodenal alimentation relieved her considerably of the gastric symptoms, so that she could partake of ordinary food after the treatment. During the cure of the ulcer, however, it was discovered that the patient's bile was frequently very turbid and oftentimes contained blackish sandlike particles which upon examination were found to consist of calcium bilirubin, so called bunch berry crystals, and mucus. (Figs. 26, 27).

About four months after treatment nausea and occasional vomiting reappeared. Finding the pylorus functioning well, I came to the conclusion that the gastric symptoms now were reflex in nature and were probably due to the gallbladder lesion; operation by Dr. Berg disclosed a diseased, shrunken gallbladder containing tarry looking bile, but no stones.

Another case of cholycystitis without stone is the following:

Case II.—Mrs. B., forty-eight years old, had been troubled for the past ten years with severe attacks of migraine and bilious vomiting. The vomiting would last for almost a day and then stop suddenly and the patient would be able gradually to resume her ordinary way of living. While at first these attacks came on only every few months, recently they had become more frequent, so that they appeared almost every two weeks. For the last year or two, she had not felt perfectly well between the attacks, being distressed for about an hour or two after meals, with heartburn and eructations of gas. A detailed examination of the gastrointestinal tract pointed to a duodenal ulcer and gallbladder lesion. The bile was always turbid in the fasting condition and frequently contained sandlike concretions of a blackish color. Microscopically numerous cholesterin and bunch berry crystals of amber color, pus cells, and epithelial cells were found. The patient was operated upon on October 3, 1923. Outwardly the gallbladder showed no evidence of disease but based upon the findings previously discovered in the bile in conjunction with the symptoms a cholecystectomy was performed by the surgeon in charge Dr. George Woolsey. Upon opening the gallbladder several ulcers were found on the mucosa of this organ, while the entire mucosa was greatly inflamed. Lying on the mucosa were found a few black sandlike particles which microscopically showed the same formation and variety of crystals as found in the bile at the examination previous to operation. (Figs. 28, 29, 30.)

A third case of cholecystitis without stones is the following:

Case III.—W. B., fifty-two years old, was admitted to Lenox Hill Hospital on January 2, 1924. He had had a nervous breakdown in 1919 and in March, 1919, was at the Lenox Hill Hospital for about ten days under my care for a gastric neurosis. He had been well until about three months ago when he slipped in the bathroom and fractured the left clavicle. Since that time he had been suffering from intermittent pains in the epigastrium radiating to the back with constant discomfort in this region. He did not vomit, but had a bad taste in his mouth and bad breath, and was constipated. On admission the patient's weight was 149 pounds. Red blood cells, 4,500,000; hemoglobin 85 per cent; white blood cells, 7,800. Gastric analysis: P. C., free hydrochloric acid, 25; total acid, 35; no blood. January 4, 1924, feces contained no blood. String test showed blood stain 50'-65' cm., bile stain 63' cm. to end. January 14th, red blood cells 4,270,000, hemoglobin 65 per cent, white blood cells 7,000, polymorphonuclears 67 per cent, mononuclears, 33 per cent. The urine contained no albumin; no sugar; white blood cells 3+, epithelial cells 2+. The duodenal contents were unusually clear, but contained several black sandlike particles consisting of calcium bilirubin and cholesterin crystals, also mucus. The second specimen showed numerous bacteria. January 5, 1924, the x ray examination (Dr. Stewart) showed

no lesion of stomach or duodenum. Tenderness on deep pressure over gallbladder region with fixation of bulbus. No retention after six hours with head of meal in ascending colon. The cecum was felt and found to be freely movable. The appendix was visible, not sensitive, movable. There was definite sensitiveness in the right hypochondriac region which was accentuated on deep pressure. The patient's weight was 160 pounds. The diagnosis was duodenal ulcer and cholecystitis. The patient was put on duodenal alimentation and operation advised.

(*To be concluded*)

Control of Hemophilia and Other Hemorrhagic Conditions*

Preliminary Report of a New Method Which Mechanically Reduces the Coagulation Time of the Blood

A. L. SORESI, M.D.,
New York

While testing a new apparatus for blood transfusion, using the distal portion of the jugular vein of a dog as the donor and its proximal portion as the recipient, we noticed that the blood, after a while, had a tendency to clot in the two needles. The flow of blood being practically constant, evidently the clotting could not be attributed to stagnation of blood in the needles, but perhaps to the fact that with the procedure mentioned above we had decreased the coagulation time of the blood.

Realizing the great clinical importance that the reduction of the coagulation time of the blood might have in controlling hemorrhage in cases of hemophilia and other hemorrhagic conditions, with the assistance and invaluable help of my assistant, Dr. W. P. Eckes, I started experimental research immediately to determine if the coagulation time of the blood could be reduced by mechanical means.

The experiments were most successful. We were able to reduce the coagulation time from an average of eight to ten minutes to an average of one minute and a few seconds. In this preliminary note we shall not dwell on the details of our experiments, nor on the theories of coagulation. We merely wish to record the fact that by purely mechanical means we have succeeded in reducing in vitro and in living organs the coagulation time of the blood circulating in healthy animals to about one tenth of the normal.

As already mentioned, the jugular vein was exposed and severed; the distal end used as donor, the proximal as recipient. An instrument, to be described later, having two automatic gravity valves to which a two and a half c.c. syringe is attached, was used. This instrument permits continuous suction of blood from the donor's vein and introduction of this blood into the recipient's vein. By filling and emptying the syringe about six hundred times, the amount of blood passed through the syringe was about 1,500 c.c. A dog, weighing about thirty-six pounds, would have about 1,500 c.c. of blood. Therefore all the blood would have passed through the transfusion apparatus, composed of small metal tubes, rubber tubes and a two and a half c.c. syringe. The average coagulation time decreased from an average of ten minutes to the lowest average of one minute with a regular rate: that is by making four tests at different intervals the coagulation time decreased thus:

First test, before autotransfusion.....ten minutes
Second test, five minutes after autotransfusion was started .....seven minutes
Third test, five minutes later.....four minutes
Fourth test, five minutes later.....one minute

At the end of twenty minutes, the coagulation time in vivo was also most markedly decreased. Notwithstanding the fact that the animals were under the influence of ether, which favors hemorrhage, the severing of the femoral vein caused only very slight bleeding, the region becoming immediately covered with a large clot.

This latter observation is of the greatest clinical importance because it demonstrates that by shortening the coagulation time there is practically no hemorrhage from as large a bloodvessel as the femoral vein. We may, therefore, logically expect that in cases of capillary hemorrhage as occurring in hemophilia and other hemorrhagic conditions, the procedure mentioned above will cause early coagulation of the blood, stopping the hemorrhage and saving the patient's life.

The simple passage of a great amount of blood through a syringe evidently decreases the coagulation time of the blood, and while we realize that this does not mean that hemorrhagic conditions can be cured by this simple expedient it gives great hope for the treatment of these very serious conditions.

Clinically it may be advisable to add some coagulating substance to the blood of the patient while the autotransfusion is going on, previously or after. Also transfusion of whole blood while the autotransfusion is going on, previously or after, may be advisable. We are working up these different sides of the complex problems of hemorrhagic diseases and hope soon to report clinical cases.

I shall be very glad to furnish additional information to any one interested in the matter, and extend a cordial invitation to colleagues to witness the work done at the Laboratory of Surgical Research, cheerfully offering my assistance gratis in the application of this treatment to any hospital patient.

Relation of Gallbladder Infection to Encephalitis

S. R. SALZMAN, M.D.,
Toledo, Ohio

The presence of epidemic encephalitis as an endemic disease, and its occasional flareup in more or less extensive epidemics, has added another to our list of diseases of unknown origin. Its importance is increased by reason of its relatively high mortality, and because of its serious sequelæ. Despite the large amount of experimentation to determine the etiology of this disease, the cause of encephalitis has not yet been found. Rosenow is of the opinion that epidemic or lethargic encephalitis is caused by a streptococcus, although this organism has not been directly cultivated from the brain tissue.

Flexner (1) in a complete résumé of all the experimental evidence published so far, concludes that only one definite example of transmission of this disease has been produced. He concludes further that the other reported positives are due to the fact that the experimental animal used, namely the rabbit, normally shows all the various findings which were reported by various observers as positive evidence of an experimental transmissibility of this disease. He concludes that the question is not yet settled. The changes which occur in the brain during the course of this disease have not been definitely determined. The pathological reports are based largely upon the very virulent cases, and on the late cases in which, no doubt, some healing and scar formation has occurred.

In view of the fact that many patients recover completely, that even after a year and a half recovery may be complete, as in Leiner's case (2), a question of doubt arises as to the pathology present in the brain tissue. It is possible, as suggested by Leiner and others, that edema may play an important part in the symptomatology of the disease. This edema may be due to a selective action of a toxin elaborated in some source of infection in the body. Among the various places in the body in which infection may be lodged, and yet be unrecognized for a long time, is the gallbladder.

I have had five cases of encephalitis associated with infection in the gallbladder or bile passages. Four of these patients were returned to normal by the surgical removal of the source of infection. The fifth patient, unfortunately, did not survive the operation, although definite pathology was found in the gallbladder. In each of the other four cases, the change in the mental and physical picture was noticed promptly within twenty-four or forty-eight hours; that is, by the time the patient was alert enough, following the recovery from anesthesia and the shock of the operation, to be carefully examined, and the mental state determined. Briefly, the cases follow:

Case I.—Miss E. G., nurse, aged twenty-six. Seen first on December 4, 1922. She complained of pain in the upper abdomen; usually came on two hours after meals; was relieved by food, but not always. Condition had existed eight months. She frequently vomited to relieve distress, but recently vomiting was worse and more marked, pain was more constant and closer to meals. The stools were clay colored; no tarry stools were noted. Her weight was stationary at 165. Had been taking a powder which gave relief for a time only.

She had had typhoid at seven; measles and diphtheria in childhood, appendix was removed five years ago, but operation did not give complete relief from symptoms.

General examination of no importance except that a slight enlargement of the liver, two finger's breadth below the costal arch, was noted; this was tender. Laboratory tests showed stools dark, of grayish black color, but no blood. Gastric analysis: no free hydrochloric acid; total acidity 23; no blood, sarcene or Oppler-Boas bacilli. Urine was negative in every way. Gastrointestinal x ray showed no changes except marked tenderness along the cecum and ascending colon, and spastic colon. Diagnosis of gallbladder disease was made, and was borne out by the surgeon's record made at the appendix operation five years previously, which showed that the gallbladder had been adherent to the stomach, had been opened, and closed after finding no stones present; also a note was made that five or six enlarged glands was present along the cystic and common ducts.

Patient entered the St. Vincent's Hospital for observation on December 20th. Shortly after entering the hospital, it was noticed that the patient's mentality was depressed; memory was poor; she was drowsy and irritable. Shooting pains in the abdomen and legs were complained of; jerking motions of the arms, legs, and fingers were noted, and patient complained of jerking of the abdominal muscles. The abdominal reflex on the right disappeared, and the left knee jerk could not be obtained.

On the 25th the patient complained of diplopia and distortion of objects, and the white uniform of the nurse appeared black. On one occasion, she saw only the upper half of my body as I entered the room. Delirium appeared at midnight, and for two or three nights in succession, patient fought with her nurse to come to my office to keep an appointment which she declared had been made.

Spinal puncture revealed fluid under slight pressure. Examination showed no globulin, Wassermann was negative, gold chloride negative, cell count eleven.

Patient's condition improved for two or three days, and then she became worse, and another spinal drainage was done. Vomiting now became persistent and severe, and always contained bile. The upper right rectus became rigid, and tenderness increased. The white blood count was 8,200. Because of the definite gallbladder picture and the persistent vomiting which made it impossible to nourish the patient, it was decided that surgery was indicated, regardless of the encephalitis. This was done January 2, 1923, by Dr. Fred. Douglass. A markedly thickened gallbladder, buried in a mass of adhesions, was found and removed. No other pathology was noticed. The re-

covery from the encephalitis was prompt and complete.

On questioning the classmates of this nurse, it was found that changes in her character, disposition, and mentality had been noticed by them as far back as February of that year.

Case II.—Mr. B. F. L., merchant, aged forty-one, This patient has been under my care since 1915, at which time he had repeated attacks of tonsillitis. He had, at this time, a moderately extensive psoriasis, which had existed over ten years, and for which treatment had been given by a number of prominent dermatologists. The tonsils were so troublesome that removal was advised, and done in April, 1915, by Dr. A. L. Steinfeld. I was very much surprised to note that within a few days the psoriasis began to disappear, and within a week was gone. In February, 1920, patient reported again because of a return of the psoriasis, which had just appeared for the first time since tonsil operation. He had, also, a very severe neuralgia, extending out from the region of the sixth dorsal vertebra along the left to the front. He complained of nausea, marked epigastric distress, and constipation. The stools were clay colored and the tongue was coated.

Nonsurgical biliary drainage was undertaken. The B bile was green and thick, containing much mucus, very little pus, but long chains of cocci were seen under the microscope. Both the psoriasis and the neuritis were improved, and a course of five drainages was given, with complete relief from both these conditions.

The present illness began early in July, 1923. Patient noticed a slight pain and discomfort in the left buttock, extending down the thigh and leg, but paid little attention to it, attributing the pain to his physical activity, until about the 18th of August, when he came to the office for relief.

The pain was definitely along the course of the sciatic nerve; did not involve the hip joint. There was already a difference in the measurements of the left leg, as compared to the right. The tendo Achilles reflex was absent, and there was marked tenderness around the head of the fibula. Patient complained, also, of a sense of a lump in the epigastrium, a mild nausea on arising in the morning; had lost about ten pounds in weight during the last six weeks.

General examination revealed nose, throat and teeth in excellent condition; heart and lungs normal. Abdomen showed a marked tenderness over the ninth right costal border. The entire right rectus was rigid; Murphy's percussion over the costal border produced epigastric pain. The spleen was not enlarged, abdomen negative otherwise. Rectal examination revealed a slightly thickened nodular prostate. Smear was negative for gonococci. Red cell count was 5,000,000; hemoglobin 90 per cent. white cells, 6,500. Urine showed a trace of sugar, no albumin, no casts, indican a trace, and ferric chloride one plus. X ray of the teeth showed no root abscesses. Blood sugar taken at this time, two hours after the noon meal, was .172 per cent; later, after fourteen hours fast, it was .113 per cent. Blood urea, 20 mgs. per 100 c. c.

The absence of any other source of infection, and knowledge of his past biliary tract involvement and present gastric distress, again seemed to point to the biliary tract as the source of infection. The prostate, however, was given a thorough course of treatment, with no improvement in the sciatica. Nonsurgical biliary drainage was again attempted, and on four successive occasions, only A bile and a very small quantity of C bile was obtained; no B bile at any time. Patient did not respond to the treatment, and because of failure to obtain B bile, he was advised to enter the hospital and to consider surgery.

Patient was then lost sight of for about three weeks. He was seen again on the 9th of October, and it was learned that he had become progressively worse. The pain was intense, and he felt miserable in general. He had lost considerable weight since last seen; skin was definitely subicteric. No examination was made at this time, as I was leaving the city for a day or so.

On the night of the 10th, on my return to the city, I saw patient about eight o'clock, and found a very marked change in his condition. There was a definite mask expression; patient was emotional; euphoria present; had had diplopia all day. His mother stated that he had used rather strong language during the day, something which he had never previously done in her presence. The tongue was coated; marked tremor was noted. The pupils showed nothing unusual. The liver was now palpable, about two finger's breadth below the costal arch; slightly tender. The abdominal reflexes on the left side were absent, on the right were diminished. Right knee-jerk exaggerated, left diminished. Patient was drowsy, slept most of the time, but could be readily awakened.

The picture was definitely that of encephalitis; and having in mind the two previous cases, together with the fact that the gallbladder was known to be infected, I advised surgery in the hope that removal of the infected gallbladder would relieve the encephalitis. Patient was taken to the hospital and prepared for operation.

By morning, the drowsiness had increased and a bilateral ptosis was present. The operation was done by Fred. Douglass, and a greatly enlarged, distended, and what appeared to be a constricted gallbladder was removed.

On opening the gallbladder, over two ounces of thick, viscid, mucilaginous bile was removed, green in color; and six or seven very small, apparently freshly formed stones, each about the size of the head of a small pin were found. These concretions were all glued together in one mass by the viscid bile, and probably formed the obstruction which prevented the gallbladder bile from emptying. After the gallbladder collapsed, it was seen that the apparent bilobed condition was really due to a diverticulum, extending from the base of the gallbladder, which, when distended, was fully as large as the gallbladder itself. The appendix was found bent sharply at a right angle with itself, and together with the caecum was adherent to the pelvis. The appendix was removed with difficulty. Culture of the bile from gallbladder was sterile.

Patient made an excellent recovery, and the morning after the operation showed just a slight euphoria. This soon disappeared, and no other signs of the encephalitis remain. Recovery was complete. Pa-

tient, however, had no recollection of the twenty-four hours prior to the operation, nor of going up to the operating room.

A few days after the operation, in talking over his illness, he stated that he probably was sicker than he realized; because for six or seven months previously, he had had no energy, he had been steadily losing in weight, he had been forcing himself to do his usual routine work, and although he had spent the entire summer at his cottage by the lake, he had gone in bathing only twice, and normally he was very fond of the water. He had not got the pleasure from his vacation that he usually did, and realized, when looking back on this period, that things did not appear quite normal, but that he had not fully realized that anything was wrong.

This is a very small list[1] from which to draw conclusions concerning such a widespread condition as encephalitis.

The importance of negative cultures from the gallbladder must not be overemphasized. No special technic was used, and no anaerobic cultures were made; the laboratory taking merely a stab culture.

It is well to call attention to the fact that in all of these cases where an accurate history can be obtained, the patient is aware that he has been ill, and mentally below par or abnormal, for a much longer period of time than at first appeared to be the case. This period of prolonged onset of encephalitis sometimes extends back seven or eight months or a year.

We must again recall here the fact that the virus of this disease has not yet been isolated. It has not been definitely shown that the virus is present in the brain tissues; bacteria have not been shown to be present in the nerve tissues. Considering this, together with the gradual onset of the disease, it does not seem illogical to assume the presence of the virus in some part of the body, other than the brain itself, from which point the toxins find their way to the nerve tissues, and by their selective action produce the changes which are characteristic of encephalitis. Should it be shown that a microorganism is the causative factor, and should this be isolated from the brain tissue, it need not conflict with the statement made above; for the microorganism might readily find its way from one focus of infection in the body to another, as occurs in the production of myositis, following cases of tonsillitis. Many other illustrations are known to all clinicians.

In connection with the part played by the gallbladder in these cases of encephalitis, I believe it is of real importance to appreciate and perhaps to give further study to an epidemic which has been prevalent in the past year, at least in this section of the country.

I have seen a number of cases, particularly in children, with fever ranging from 102° to 104°; headache; coated tongue; indefinite abdominal pain; leg pains; and rarely, epistaxis. There was occasional vomiting. Nearly always the upper right quadrant of the abdomen was rigid, and always tender. The stools, on the second or third day, began to vary from light yellow, to clay color. Not infrequently, two or more children in the same house would come down with the same infection within a few days of one another, and occasionally an adult in the house would show the same symptoms. The severity of the disease varied considerably; the fever lasted usually from two or four days, occasionally longer. However, no jaundice was observed in any of the cases, but many of these youngsters had a very slow convalescence, and it was weeks and occasionally months, before they were again perfectly normal.

Unfortunately, because of the mildness of the infection, and because all of these patients were seen in the home, blood studies were not made, nor was it possible to attempt isolation of the spirochete associated with acute infectious jaundice which the cases resembled.

I am sure that all physicians in general practice have noted the increasing number of gallbladder infections prevailing during the past few years. In my own work, I have seen at least five cases of acute gallbladder infection to one of acute appendicitis; chronic and subacute gallbladder conditions also numerous. This has been the experience of a number of surgeons to whom I have spoken on this subject.

That all cases of encephalitis are associated with gallbladder infection need not follow. As an illustration of this, I might state an earlier experience. Early in April of 1918, I saw a man of thirty, a bartender, taken sick with severe, unbearable shooting pains in the left side of his face. In severity and distribution the pain suggested tic douloureux. This persisted for nearly a week. Patient then began to run a temperature, running from 99° to 101°; complained of terrific headaches; became drowsy, and, at times, stuporous. A slight rigidity developed in the left arm and leg; twitching of the muscles of the face; finally, within a day or so, severe generalized convulsions occurred, becoming very numerous up to thirty a day. Some beginning changes were noted in the eyegrounds, suggesting a beginning choked disc, and patient went into a state of stupor from which he could scarcely be aroused.

Diagnosis of brain abscess was made and was confirmed by Louis Miller. The abscess was considered to be in the Rolandic area on the right side, and a decompression operation was done by Homer Heath. No abscess was found, but the entire exposed area of the brain showed intense vascular engorgement, and a few minute hemorrhagic spots were seen. The picture resembled that of an encephalitis. The possibility of encephalitis, secondary to marked dental infection was considered, and twenty infected teeth were withdrawn two days later. From this time on, the patient had only four or five convulsions. Improvement was rapid; patient made a complete recovery, and was out of the hospital within two weeks. Was last heard from in 1921, when he considered himself in perfect health, and had gained over twenty pounds in weight.[2]

Peter Bassoe, in his discussion of Hunt's paper on encephalitis, (3), says in part: "We must assume that the virus may lie dormant in the brain as the

[1]Three additional cases have been omitted due to lack of space. Since submitting this paper for publication another severe case was seen. Removal of gallbladder resulted in prompt recovery.

[2]This case is very briefly reported, because it was reported by Dr. Heath in a paper read at Lima, Ohio, before the Tri-State Medical Association. Still unpublished.

spirochete in syphilis does before it produces general paralysis; or possibly the virus may remain in another part of the body, for instance in the liver or some other internal organ, until some condition mobilizes it, so to speak, so that it again gets an opportunity to show its affinity for the brain."

I believe that this suggestion is a logical one, and worthy of serious consideration. There may be some association between these various obscure fevers which have been present ever since the influenza epidemic began, and the localization of this virus in some organ of the body from which it finds its way to the brain, producing an encephalitis. I believe that the subject of encephalitis deserves further study from this angle.

Hypertrophic Pyloric Stenosis in an Infant

HARRY APFEL, M.D.,

Brooklyn.

Case.—A female infant, eleven weeks old, the second child of healthy parents. The family history was of no importance. Mother gave no history of miscarriages. The patient was born at full term, spontaneous delivery, birth weight about seven pounds, present weight five pounds and nine ounces.

The child was breast fed up to four weeks of age when it was weaned upon the advice of a physician, for its constant vomiting. The vomiting, however, continued even after the baby was put on a formula; it was projectile in character, occurred soon after feeding, and was accompanied by a good deal of restlessness and crying. The appetite was good, stools two to three a day, very small and yellowish. Failure of the child to gain in weight was responsible for frequent changes in the feeding formula.

Examination showed the following: A female child, much undernourished, scalp covered with a thick scaly eczema, eyes sunken, mouth dry, tongue reddish and raw looking, lips dry, cheeks sunken, chin pointed, ears prominent and protruding, ribs prominent, respirations regular, cardiac apex impulse visible in the fifth interspace and left nipple line. The lungs were negative. The abdomen was rounded, somewhat distended and tympanitic.

Soon after a feeding was given, peristaltic waves could easily be seen passing from left to right, in the region of the stomach. These waves would subside as soon as the baby vomited up the greater part of its feeding. The vomiting was projectile in character. No tumor mass could be made out by palpation over the abdomen.

The infant was admitted to my service at the East New York Hospital with a diagnosis of pyloric stenosis. An x ray examination made by Dr. L. Rein showed the following: The first exposure taken soon after a feeding, showed the stomach full with no food having gone through the pylorus into the small intestines. At the end of three hours, following a barium sulphate feeding, the stomach was three quarters full and only little food had trickled through the pylorus. At the end of four hours, the stomach was still half full with only very little more shadows over the intestinal field. At the end of six hours there was still a residue of one third of the meal in the stomach. On each plate, the stomach presented an hourglass appearance.

The diagnosis of hypertrophic stenosis of the pylorus was corroborated. Owing to the extreme emaciation and great loss of weight, the infant weighed only five and a half pounds, and the rather definite symptoms, immediate operation was decided upon without further experimenting with drugs, thick farina feeding or passing a duodenal catheter (1).

Dr. A. Lightstone performed a Remmstedt operation under oxygen-ether anesthesia. A hard cartilaginous tumor of the pylorus was found which was incised down to the submucosa, and the abdominal wound closed.

Two hours after the operation the child was given its first feeding. The reaction following the operation was mild; the temperature going up to 104° F. which remained up for twenty-four hours. Two hypodermoclyses of normal saline administered the day following the operation brought the temperature promptly down to normal. The child then took its food well, spitting up a small amount once or twice a day.

The child was weighed on the seventh day following the operation, and it showed a gain of seven and a quarter ounces. On the ninth day after the operation, the baby was taking a two and a half ounce milk formula and retained it. Did not vomit, had two to three yellow, soft stools daily, appeared well, rested comfortably and gained eleven ounces since the day of operation. This was the first time this child had gained weight since it was born. No atropine or any drug was given to the baby at any time since it came under our care.

Examination of the patient on the day of discharge from the hospital, two weeks after operation, showed a gain of 19.5 ounces since the day of operation. The child took its food and cried soon after the bottle was emptied. There was no vomiting and the bowels moved two to three times a day, the stool was yellowish and pasty. The child slept comfortably. The wound healed and the general condition was satisfactory.

Fig. 1.—Baby F. Three hour picture. August 20, 1922.

REMARKS.

The management of this condition is still open to discussion inasmuch as there seems to be a considerable difference of opinion as to the actual existing pathology. As long as the profession will adhere to the theory of spasmophilia in all cases presenting persistent vomiting, until the patient is in such a state of starvation that the risk of operation becomes extreme, it naturally follows that the operative treatment will not gain many followers. It goes without saying that when the child first begins to vomit, atropine or lavage is the proper routine. However, weaning a baby for the simple reason that it vomits, is, to say the least, using poor judgment. It is important to emphasize the fact upon the practitioner that there is a difference between a child's spitting up part of its food, and progressive and forcible vomiting of the greater part of each feeding, attended with progressive loss of weight and emaciation.

While every case of true pyloric spasm presents visible peristalsis, a palpable tumor, however, is felt rarely and even in the same case, it can only be made out after the patient is fairly well dried up as a result of prolonged starvation, and therefore it is dangerous to wait until such a time when a tumor can be felt. The best way to elicit visible peristalsis is to give the baby its food and then with the patient on the table in front of a good light carefully observe the wormlike movements through the abdominal wall.

Fig. 2.—Same case. Four hour picture.

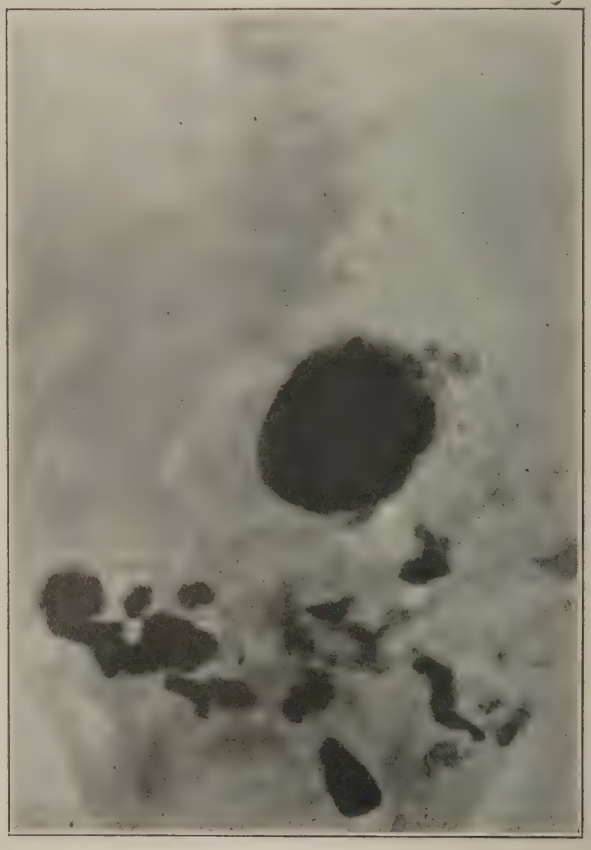

Fig. 3.—Same case. Six hour picture.

REVIEW OF SOME OF THE LITERATURE ON THIS SUBJECT.

Dr. Wollstein (2) reports a study of twenty-five cases of hypertrophic stenosis of the pylorus that came to autopsy. She cites the pathology to be a hyperplasia of the unstriped muscle fibres of the circular coat of the stomach. There was no connective tissue increase. Those patients of the group which had been operated upon and a gastroenterostomy was

performed, usually died as a result of failure to cure the pyloric lesion.

The Remmstedt operation does effect a cure of the pylorus. The incised muscle wound fills up with connective tissue, which process is usually complete within nine days.

Ernberg and Hamilton of Stockholm (3) have treated medically fifty-seven cases in ten years with a mortality of only three and one half per cent. They find in their series of cases that lavage nor drugs have in any way influenced the results. They conclude from their observations that most of the cases will come to a spontaneous recovery if we could only keep the patients up long enough by the administration of a sufficient quantity of fluids by way of hypodermoclysis.

Wall (4) says, "A strong belief in the spasmodic theory would tend to jeopardize the life of an infant through delay, incident to medical treatment.

Rachford (5) states that early operation is indicated in clearly defined cases that do not yield readily to medical treatment.

Professor Schick of Vienna (from a personal interview) entertains a conservative view on this subject. He believes entirely in the condition being a neurotic tendency on the part of the child and for that reason he advises against any operative interference and only resorts to operation as a last remedy. The results on cases operated when extremely emaciated, are naturally not encouraging.

Morgan (6) reports fifty cases of pyloric stenosis that have been treated at the Babies' Hospital in which the following points are worth noticing. Namely: The average duration of illness preceding operation was seven weeks. The average weight of these fifty cases the day of operation was six pounds three ounces. Twenty cases showed a loss in weight, postoperative, ranging between three and five ounces.

In fifty per cent. of the children upon which a gastroenterostomy was performed, there developed a severe diarrhea. Their mortality was twenty-eight per cent.

RÉSUMÉ.

1. Make the diagnosis as early as possible.
2. Do not condemn the mother's breast milk where the fault may be with the mechanism of the baby's digestive organs.
3. Resort to antispasmodics or lavage as early as possible; but discard them after one week's trial has given no results.
4. Give the child the benefit of surgical relief while its health is still in fair condition.
5. When operation is decided upon let it be a Remmstedt operation and not too much surgery.
6. Commence feeding as soon as the infant has recovered from the anesthetic, and increase the quantity of the food as the baby's food tolerance increases.
7. A conscientious and experienced nurse is one of the factors that will count towards the result of the treatment.

The Wanderlust Impulse

P. R. VESSIE, M.D.,
Gowanda, N. Y.

Wandering is a perpetual holiday in the great scheme of nature. By a mysterious intelligence the wandering red corpuscle masters the life of a cell. In the air the migration of birds is also a notable form of wandering for a purpose. The sea is full of wanderers. Prehistoric man was a wanderer when he lived in trees, but in the cave and cliff dwelling ages his wanderings must have been circumscribed. If modern man originated in central Asia, as some ethnologists believe, it is only by a succession of wanderings that the earth has been peopled. The Romans wandered around the known world sword in hand and founded a mighty empire. Columbus wandered across the Atlantic and discovered a new world. The Pilgrims wandered thither and founded New England. An endless succession of hardy pioneers wandered westward and made America one of the foremost of modern nations. The Phoenicians wandered in their ships in quest of commercial gain. Pizarro and Cortez and many another unscrupulous navigator sought the "treasures of the mine." The Crusaders wandered to Palestine to wrest the Holy Sepulchre from the Saracens. The intrepid young man finds the lure of the frozen North with a dog and sledge irresistible, while the more languid temperament seeks a paradise on some South Sea Isle. The lure of gold enticed thousands of wanderers to Australia, to California, to Alaska, and it is the same glittering lure that animates that typical lifelong wanderer, the mineral prospector. The love of souls moves the missionary to wander, like Livingston, through heathendom. The desire for knowledge leads scientific explorers and even romantic writers to the remotest corners of the earth. Hunters of big game, singers, actors, commercial travelers, are all regular or occasional wanderers in quest of sport or fame or money. The gypsies and the nomads of Arabia are typical wanderers. The adventurous vagabond inherits a mania for gypsy life, just as the bandit is

born with the longing to hunt human game, and in the great field of misdirected ambition, we observe that even the "holier than thou" hypocrite often has a congenital lust for some sly, subterranean life.

The human race since the dawn of history has vibrated between the two extremes of *wanderlust,* an overwhelming desire *to go,* and *bleibenlust,* an equally strong desire *to stay.* Of two brothers born in the same valley one may be perfectly content to spend his whole life there and the other may be consumed by a restless desire to see the world that lies beyond the horizon rim. In the peasant class of humanity this stay-at-home disposition is generally prevalent, and only some great misfortune, like war or famine, is likely to set them adrift. While wanderlust is a true impulse, the expression of a longing for the "land of freedom" by those who suffer squalid, miserable and unbearable home conditions must be viewed with a feeling of pity. The selfsupporting wanderer, with some worthy or at least harmless purpose in view, may be tolerated or approved or even admired. On the other hand, the genuine wanderlust inspires a young man, or very often a mere boy, to abandon all the comforts of home for the pleasure of roaming around the world, "strange countries for to see." He is not in quest of anything intrinsically desirable, and never asks himself for what purpose he leaves the worn paths of ordinary life.

Many years ago, Moody and Sankey and other successful revivalists often used a song with the touching refrain: "Where is my wandering boy tonight?" They of course intended it for the great mass of mothers, and well they knew the emotional effect it would produce, so countless was the caravan of roving sons who had never returned home. Out of the commonplace thousands who pass unnoticed there emerges a leader, The Beloved Vagabond, a very familiar hero of human interest on the legitimate stage, on the movie screen and in the popular novel. Although in reality a worthless and lawless scamp, many tales of romantic adventure are told of him and the admiring, sympathetic crowd, with a secret longing for adventure, action and an easy life, seldom pauses to wonder why it glorifies this parasite who persistently avoids labor and cherishes the brainless theory that the world owes him a living. The habitual tramp even believes his life to be an ideal one and is really proud of it. He resents the restraint of organized society and to him the law of the land is a persecution to be evaded.

This illogical creed is idealized by higher types of sentimental wanderers, such as Walt Whitman, who represents the gypsy trail as a land of sunshine. Such independence without progress is typical of many cranks, who, sooner or later, exhibit mental tendencies which mark them as psychopathic, epileptic, dementia precox, or manic depressive victims. This philosophy is best interpreted by the hobo (1) himself:

> "The hobo is a pioneer. Call him a throwback if you wish, but in a society that is becoming feminized, under luxury known in ancient days to be woman's, man becomes soft, flabby, slow of brain and slow of body.
>
> "Not so the hobo. He seeks the unknown. In him the restlessness of life speaks more loudly and responds to cosmic calls. The road beckons, the mountains call, the sea murmurs and the brain pleads, 'Let me know. Let me learn the way of all things.'
>
> "The greatest thinkers have been men who had leisure and time to observe—to ponder—not the wage slave, stunted and crippled physically and spiritually.
>
> "You could go back to Socrates, further to Moses, to Christ, down to Jack London and Gorky. 'To live, not to vegetate; to think, not to exist; to dream, not to wither and decay,' for as Harry Kemp, the poet, puts it, 'At best a dream is all that we get.'"

The simple fact that we are ingrained with emotions and that they tend to overbalance the intellect explains why a vagabond who lacks the power of selfrestraint finds it impossible to socialize himself to meet the demands of decent society and thus promenades unashamed on the public highway. The instinctive contempt for culture and social conventions, the lust of the body for bohemianism, the inability to conform to a strain, the wayward impulse misdirecting a great deal of energy are the signs which measure the limited value of such a personality. In this gallery of shiftless renegades are included the seasoned tramp, the millionaire hobo, the lawless gypsy, the hospital rounder, the race track tout, the circus follower, the soldier of fortune, truant, rogue, peddler, beggar, vampire, continental swindler, daredevil and black sheep. They all belong to the same group, but are of a different shading with regard to character. Their interpretations of the principle of life differ and they therefore take the open road in different directions.

Many tourists, commercial salesmen, missionaries, journeymen, professional men, artists and explorers reveal an unsettled feeling, a driving force, which compels them to move on to new fields, and their power of adapting themselves to circumstances and conditions, as we all know, is truly remarkable. Although the vagabond contributes nothing of value to the world, he derives the same pleasure from his wanderings. This habit of shifting about gratifies the natural inclination called lust, and serves as an outlet for unstable emotions. To settle down would be a cruel restraint for such wanderers because the periods of unrest always create an impulse to be "on the go"; their restless conduct is very similar to that of the addict who has not taken his regular dose of morphine, but others fail to see a logical motive for the departure.

Referring to Kraepelin's (2) description of the fundamental states of the manic temperament, one can readily understand this wanderer's impulse to an inner overactivity or constitutional excitement, the symptoms of which indicate a slight hypomanic condition:

> "In the conduct and the activities of the patients a certain unsteadiness and restlessness appear before everything. They are accessible, communicative, adapt themselves readily to new conditions, but soon they again long for change and variety.
>
> "Already at school they are insubordinate

and disorderly, ringleaders in all disturbances of the peace; they play truant, run away, do not get on anywhere, have to change their school, fail in examinations, because of their aversion to thorough and persevering study.

"The aimlessness of their procedure is sometimes very peculiar; it distinctly shows how little the inner pressure of activity is guided by sensible deliberation."

Not infrequently such cases assume a depressive phase for weeks or months, and during such a mood do not travel. The wander impulse in the manic depressive is a sudden rush of nervous energy of which mobility is a dominating symptom. The actions and thoughts during this mild manic flare up are cleverly rationalized by the individual and when in the quiescent period which invariably follows, he realizes that he was ill and suffered undue restlessness. His true lust to travel is probably an unconscious effort to flee from his mental tangles.

During times of unemployment certain types, through idleness, become introspective and lazy and soon show a disinclination to lift themselves out of their destitution. They later drift about, become drunkards, steal, beg and deteriorate. The habitual loafer or bum is perhaps the greatest menace to a community, lacking fundamentally in character and devoid of all selfrespect, standing about apathetically, spineless and lazy, slipping through life with the least possible friction. Such creatures are easy subjects for the grasp of the law and are often mistaken for the ruffians (psychopaths, defectives, manics) who deliberately look for brawls. As Kraepelin and others consider that a well marked manic or cyclothymic predisposition rarely leads to dementia precox one can hardly fail to relegate the above group to the dementia precox classification, in view of the deterioration which ultimately results. William H. Davies, a genuine tramp and beggar with literary talent, wrote with rare appreciation of his weakness: "Certainly I have led a worthless, wandering and lazy life, with, in my early days, a strong dislike to continued labor, and *incapacitated from the same in later years.*" White (3) remarks on the *simple* type of dementia precox:

"A study of this class of cases shows quite frequently that the patient's resort to a hobo type of existence has been the result of his inability to adapt himself to the ordinarily complex conditions of social life, in other words, that he has slipped from under all responsibilities and all conditions which involved continuity of effort and industry. He goes from one position to another, unable to fulfill even the simpler duties because of his lack of continuity and interest."

In the paranoic type of vagabond the majority are everlastingly driven by persecuting voices and delusions, and attempt to find some avenue of escape from this product of their own imaginations. In the catatonic form, confused wandering occurs during the appearance of excitement which often is alternated by the phases of catatonic stupor and catalepsy at which time they are picked up in the streets, as is noted almost daily in newspaper dispatches. The hebephrenic type wanders because he is a buffer to any social environment and the instinct to avoid the broadside of a difficulty causes him to detour automatically from place to place. Such cases seldom choose a given destination; what they see is of no particular interest to them, and, owing to their progressive deterioration they are sooner or later sent to state institutions.

The man who has been wandering over the globe for a definite purpose is always glad to return to his homeland while the butterfly psychopath who spends his whole life in senseless wandering is seldom attacked with a fit of homesickness, owing to the lack of a certain moral sense. Although this desire to roam is a natural impulse in every heart, society puts a ban upon it. The average man does not express discontent over being compelled to remain at home for fear of being regarded as unstable or dissatisfied with life. He faces the unpleasant things in everyday existence, while the vagabond with a pathological personality runs away from difficulties. The latter changes his scenic environment so often, not because he is in search of the beauties of nature or for educational purposes as he would have us believe, but as an instinctive means of selfpreservation, which prompts him to flee from his home surroundings to foreign regions where he can remain unmolested. Knowing that he is temperamentally not constituted to withstand the tedium of associations very long, it is a hardship for him to sustain a normal mental, physical and moral balance. The beggar-tramp of the psychopathic group is difficult for uplifters and penologists to analyze because he himself is a very clever psychologist. He will try to rationalize his unstable acts and give a motive for his disordered conduct. While psychopathic vagabonds differ in mental endowment, some types measure considerably over the average intellect, such as the professional criminal of the metropolis who follows his vocation by choice and never will reform for the simple reason that he is morally unfit and unable to realize the evil of his particular weakness.

Temporary states of nomadism (4) are familiar in senile dementia, epileptic confusion, hysterical fugues and acute alcoholic psychoses. In the early stages of general paresis, the subject is often prompted to wander by some insane motive. In fact the moron is almost always compelled to travel because he is a harassed social misfit.

Abnormal wandering is a poison which debilitates humanity, for without moral health there can be no physical culture. The cinema is an influence upon any individual with a wayward imagination, and the Nick Carter style of story is responsible for the wrecking of many young lives, by implanting injurious suggestions in the immature receptive mind. The susceptibility of these young men to such evil influences can be controlled by explaining to them the pathology of their actions, so that when they are aware of an approach of restlessness they can immediately curb the impulse to wander and turn their energy in a healthy direction. Vagabondage has developed into a national institution in America because a police and hospital system of managing the conduct of the tramp is quite impossible. This is due to the vast acreage of our country. But the

possibility of corralling this parasite was made known in the Great War when a mass attack by the people caused him to be brought in to fight and work. During that period, an inconceivable amount of human energy which would have otherwise been wasted was appropriated to a useful purpose.

Granville Stanley Hall, 1846-1924

F. H. HANKINS,
Northampton, Mass.

It is probably safe to say that no single person has influenced both educational and psychological opinion and development in the United States during the past fifty years to the same extent as G. Stanley Hall. This he did partly by his marvelous capacity to assimilate an encyclopedic range of information, partly by his great industry in writing and speaking, and partly by his unusual capacity to inspire an interest in research in others. During a full half century he was without doubt the most consistent reader in America, if not in the world, of the voluminous educational and psychological literature of all countries. Finding his early inspiration in Germany in the middle and late '70's he became the first physiological psychologist of note in this country. At Johns Hopkins he founded the first American laboratory in experimental psychology and later, as organizer and president of Clark University, he made of that institution the training ground for a large number of embryonic psychologists who have since become outstanding promoters of psychological research and a powerful influence in the reorganization of educational thought and practice throughout this country. His influence in these fields was enormously increased by his lectures, his contributions to various periodicals, popular and scientific, and his books. Especially noteworthy was his establishment in 1887, mainly out of his own funds, of *The American Journal of Psychology,* the first American journal devoted exclusively to this science. This was followed in 1891 by *The Pedagogical Seminary,* the oldest American educational quarterly, which, largely through the indefatigable labors of Professor William H. Burnham, has ever since given a summary of international educational literature besides publishing a vast number of original investigations. President Hall was also responsible for the establishment and maintenance for a number of years by Clark University of *The Journal of Religious Psychology* and *The Journal of Race Development* (later called *The Journal of International Relations*). While the main editorial work on these journals was done by his colleagues of the Clark faculty, their original conception and impetus was due to him and to them he contributed more or less frequently. A list of his writings prepared ten years ago included 328 titles, while during this last decade he published his *Senescence,* and his autobiography.

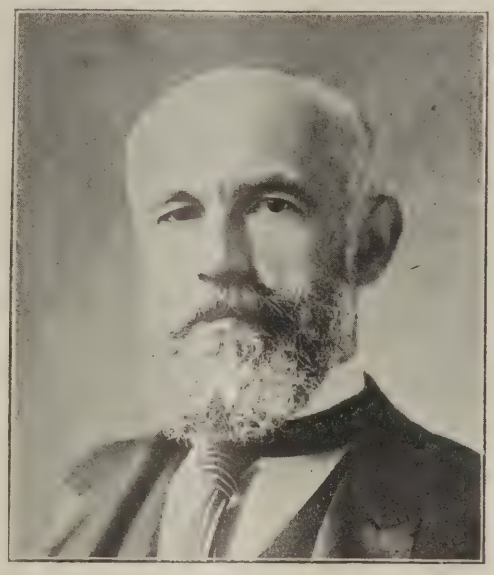
In these journals is reflected not only the extraordinarily wide scope of his intellectual interests but his capacity to find fresh trails for intellectual inquiry. Nothing is more remarkable about his long career than his capacity to maintain his mental freshness, the spirit of intellectual adventure, and youthful keenness for the pursuit of knowledge along new lines. His primary interests moved from philosophy to evolution and physiological psychology, then to child study and adolescent psychology; later he turned to psychoanalysis, religious psychology, senescence, and the feelings, emotions and sentiments. Scattered all along the line were numerous articles on a great variety of psychological and educational problems. It was a fundamental article in the faith he lived by that there was vastly more to be known than has thus far been discovered, that the sciences are still in their infancy and hold out for the exploring mind greater glories and for an expectant humanity greater hopes of deliverance than all the past has revealed or accomplished. Like an early contemporary, William T. Harris, former United States Commissioner of Education, he knew and admired Hegelian philosophy, but unlike him he never committed himself so thoroughly to the ponderous and sterile speculations of metaphysics as to lose his rapport with the ever new and developing world of thought. Gifted with capacity for literary expression, he manifested a fondness for erudite phrases and esoteric terminology and doubtless often fell a victim to the deceits of language and the plausibility of a smoothly flowing phraseology, but he was saved by an ever fresh imagination and perennial youthfulness of spirit from the dry rot of intellectual stagnation and contentment with an outworn verbiage.

He was in fact as much poet and seer as scientist, if not more so. He remained to the end somewhat of a mystic and prophet. During the last decade he spoke often of the possibilities of a "new dispensation" for man in which civilization would enter on an entirely new era, free from most of the ills which make this life a vale of tears. He thus manifested an ever renewed hopefulness and a persistent optimism. There was about him, in fact, along with prodigious learning and broad experience, an undoubted historical and sociological naiveté which evidenced the idealist and dreamer. Far from arriving at the complete sophistication of the cynic he indulged his humanitarian longings (he early studied for the ministry) in writing a Utopia.

Born in the rugged hills of western Massachusetts in 1846 he traced his ancestry back on both sides to the Mayflower, his father being a descendant of William Brewster and his mother of John Alden.

Heredity gave him a vigorous constitution, longevity, and intellectual power. Two of his immediate relatives lived beyond ninety years, one to nearly ninety-nine. Those who have seen him in recent years working away with great industry, little recreation and only incidental attention to his physical well-being believe he might well have lived another decade. He took pride in his physical adaptability, his capacity to use tools and perform various handicrafts learned on the New England farm two generations ago. Some of us who a few years ago were only half his age have marvelled to see him running for a street car or climbing the long flight of stairs in the main building two and three steps at a time.

Perhaps heredity had something to do with his choice of a profession also, for both his parents and several of his aunts were teachers. He entered Williams College with the class of 1867. One of his intimates, Francis Lynde Stetson, says: "I well remember the day I first saw him, a green freshman, nailing an iron latch on the door of his room in West College. I was captivated at once by his fine head and his glorious eye, and returning to my room said to (Hamilton Wright) Mabie: 'I have seen a man.'" After graduating from Williams his educational training was most unusual in its breadth and variety. He spent a year at Union Theological Seminary, for his parents wished him to be a minister. Then came nearly four years of study in Germany. Returning to Union for his B.D. he accepted the pastorate of a little missionary church in Pennsylvania. Preaching, however, appealed to him less than teaching, for after ten weeks we find him back in New York serving as tutor in the family of Jesse Seligman, the banker. After one year he went to Antioch College and then to Harvard, for four and two years respectively. At the latter he taught sophomore English, studied philosophy and psychology under James, Bowditch, Everett, Bowen and Palmer, and took his Ph.D. He then spent two more years in Germany, making in all six years in that country during the period of its greatest intellectual pre-eminence. There he studied both widely and deeply under such world famous scholars as DuBois-Reymond, Virchow, Paulsen, Ludwig, Helmholtz, Wundt and Fechner.



G. Stanley Hall

He was a student in Wundt's laboratory for experimental psychology almost from the moment it was opened; and shortly after his return established the first similar laboratory in this country. Among his students at Johns Hopkins were Dewey, Cattell, Jastrow, Donaldson, Burnham and Sanford. On his election to the presidency of the newly founded Clark University in 1888 he resigned from Johns Hopkins and spent a full year abroad interviewing scholars and investigating the organization of universities and research throughout Europe.

Space permits scarcely a reference to the checkered career of Clark University. No institution of learning was ever more brilliantly conceived. Designed for research and graduate instruction only, its early faculty probably combined a greater galaxy of scientific talent than any university America had ever known. Deprived of a large part of its financial support after the third year, the university was reduced to a mere skeleton. For this miscarriage of a plan so full of promise for the advancement of science both gods and men must be blamed. Nevertheless, through the untiring efforts and devotion of Hall and his handful of remaining associates the university was saved. In it the spirit of free intellectual inquiry and eagerness to extend the bounds of knowledge flourished as they have not elsewhere in this country except at Johns Hopkins under the incomparable Gilman. Like the latter Hall was above all a teacher and inspirer of wide and varied scientific investigation. Though small in numbers the university was remarkably productive in scholarly output and became known to scholars in all countries. How much more of a tragedy it must have been for Hall during the last two years as he observed from across the street the rapid and almost ruthless destruction of the Clark he had fostered with so much care and travail! In silent pain he witnessed the dismantling of one department after another, and, above all, the annihilation of the precious and delicate spirit of intellectual freedom and eager search for that truth that shall at last make man free. And yet both his faith and his magnanimity were shown in his leaving his residuary estate for the perpetuation of the study of genetic psychology at Clark.

John Ferriar (1761-1815).—John Ruräh (*Annals of Medical History,* December, 1921), says that in view of the present interest in spiritualism and other mediumistic phenomena, it is interesting to review Ferriar's *Essay Towards a Theory of Apparitions.* . . . His views on the subject are most sane. He admits that it is an undeniable fact that the forms of dead or absent persons have been seen and their voices heard by witnesses who are trustworthy. "We may be allowed, however, to enquire," he writes, "whether the improved state of physiology affords any glimpse of light on this subject, and whether such extraordinary and terrible impressions cannot be explained from the known laws of the animal economy, independent of supernatural causes."

Practical Therapeutics

TREATMENT OF ACUTE AND CHRONIC POLYARTHRITIS, ARTHRITIS DEFORMANS, AND SEPTICEMIAS, WITH ACTIVATED COLLOIDAL SULPHUR

W. J. Monaghan, M.D.
and Frank Garai, M.D.
Hudsey County Hospital, New Jersey

INTRODUCTORY

The last three decades have shown marked progress in the development of the science of therapeutic measures. New positively acting drugs of which Ehrlich's 606 and Bayer 205 are probably the most conspicuous, have been evolved and tested; the most important results were gained in intensification of older therapeutic agents such as arsenic, mercury, antimony and bismuth by converting them into proper organic salts thus gaining higher therapeutic activity with corresponding lowering of toxicity characteristic of these elements. Certain of the recognized germs have succumbed to serums and vaccines. The search for prearations that will combat the pyogenic organism responsible for rheumatic and arthritic conditions has gone on steadily in the fields of chemotherapy and serotherapy.

The general rheumatic and arthritic conditions vary widely in their clinical aspects; they also show a wide variation of causes primarily responsible for their manifestations. Every practitioner is familiar with many types of acute and chronic rheumatic and arthritic clinical manifestations arising from infections from pyogenic bacteria. He is also familiar with many cases where the causes can be traced to faulty metabolism and abnormal sensibility to foreign proteins. With such widely varying etiological factors, the profession is not to be criticized for not having developed one therapeutic agent that could be used in the treatment of all these manifestations.

SULPHUR THERAPY

From times unknown Nature has been called upon to assist in the cure or to benefit the patient where there was available no drug of positive action. The curative properties of radioactive, iodine and sulphur springs have been known and empirically utilized since the dawn of history. The beneficial effects of some of these springs were recognized long before radium and iodine were isolated as chemical elements. The beneficial effects of sulphur springs were recognized before sulphur was put into its active form by means of chemophysical processes. Such sulphur springs as Aix, Amelle-les-Bains, Bagneres de Luchon, Bonne (France); Harkany, Herculesbad, Mehadia, and Teplitz-Trencsén, Pöstyèn (Hungary); Ischl (Austria); Mount Clemens (Michigan, U. S.), have well established reputations as being highly effective in the treatment of rheumatic and arthritic conditions arising from infective or metabolic causes. They have also shown their beneficial effects in other acute and inflammatory conditions.

The reasons underlying the results obtained at the sulphur springs when using the waters, vapors, and mud could not be satisfactorily explained for a long time. The sulphates of sodium, magnesium, potassium, lithium, and others, the chief constituents of these waters, do not have any specific effect on pyogenic organisms. Sulphur in its usual elementary form as known to the pharmacologist is not readily absorbable by the human organism; and when given internally in the form of socalled washed sulphur or flowers of sulphur, it is excreted almost completely in the same form as that in which it was consumed.

About 1830 it was recognized by a Hungarian druggist that some of the sulphur springs contained slight traces of elementary sulphur in a peculiar form which passed through filter paper and which did not settle except after several days' standing and exposure to light. This discovery occurred several years before some of the principles of colloidal chemistry were developed by Graham. In more recent times this form of sulphur was recognized to be colloidal in character produced by nature, mostly by the influence of light on sulphurated hydrogen present in the water; the catalytic action of light gives rise to a reaction combining the oxygen of the water and the air with hydrogen of the sulphurated hydrogen molecule present in the spring water thus liberating free sulphur partly in colloidal form according to formula $2H_2S+2O=2H_2O+2S$.

This was the origin of the idea that the sulphur element could be prepared in some active and absorbable form resulting in a potent therapeutic agent. Recognition of the beneficial effects of sulphur and the desire to find some active and reliable form led to various experiments recorded in voluminous American and European literature.

We need only mention in passing, the time honored family remedies such as sulphur and molasses, sulphur and cream of tartar, and a combination of the three; the attempts to influence pulmonary conditions by inhalation of air containing slight traces of sulphur dioxide and the partially successful attempt to treat gout and other rheumatic conditions by the administration of flowers of sulphur and very weak solutions of sulphur dioxide. Here an interesting bit of history arises. The method of inhalation then called fumigation was practised in American therapy as early as 1820 and described by Revere of Boston in 1822 under the caption Origin and Facts of Sulphurous Fumigation in the Cure of Rheumatism and Gout.

Some of the most interesting experiments in the administration of sulphur have been practised by recent French and German investigators; they injected intramuscularly and subcutaneously finely divided sulphur suspended in eucalyptus oil, olive oil and glycerine and reported favorable results. The method just described, however, could not become popular because of its painfulness and inconvenience to the patient. The French investigators then turned to colloidal preparations of sulphur but encountered the difficulty of being unable to produce a preparation which would be stable and reliable. The following table attempts to illustrate in more or less graphic

Used in the treatment of	*Europe*	*United States*	*Used in the treatment of*

form the progress in the art and science of utilizing sulphur as a therapeutic agent.

SULPHUR IN BODY CHEMISTRY

Sulphur is one of the elements which is absolutely essential to life. It exists in various organs and body substances in amounts bearing between one and two per cent. (albumen and proteins). The varying immunity to pyogenic organism and predisposition to rheumatic joint conditions are believed by many to be caused by disturbances in metabolism of sulphur and consequent disturbance in the nitrogen body chemistry. The generally recognized but not so universally used methods of sulphur administration previously described probably can trace their success to the facts just recited.

ACUTE POLYARTHRITIS AND CHRONIC ARTHRITIS DEFORMANS

In the practice of the writers at Hudson County Hospital, New Jersey, many cases of polyarthritis and arthritis deformans in various forms are encountered. Most of these are chronic with intensive joint involvements. In the treatment of these cases, vaccine and serums are of little help. In fact more help is to be expected from such agents in acute conditions. In the treatment of such chronic cases, the writers found such therapeutic agents as salicylates, iodides, atophan of little benefit. Accordingly, the writers looked for some material or preparation which would have germicidal properties covering various strains of streptococci and staphylococci, that is, a group of pyogenic organism and which also would raise oxygen metabolism of the body.

For their purpose in the treatment of cases to be described later, the writers selected a preparation known as 338 which is activated colloidal sulphur. This preparation contains element sulphur in a particular dispersion and possessing an electric charge rendering it highly physiologically and chemically active. By the application of radioactivity as an agent in the process, a stability of the preparation is obtained without the use of organic stabilizing substances such as albumen, gelatin and proteins which are used in other colloidal preparations for stabilizing purposes. Those substances render intravenous administration of such protected colloids often hazardous since they produce reactions of their own and furthermore may produce anaphylaxis; as applied to sulphur element such protective colloids may destroy entirely its germicidal properties and reactivity. Due to the purity of the preparation 338 the intravenous method of administration was adopted in the treatment of all cases coming under our care although on occasion internal sulphur administered orally was used to supplement the intravenous method.

ROUTINE OF INJECTION OF 338

The preparation used contains approximately twenty milligrams of sulphur element to one cubic centimetre of solution. One third to one half milligram of sulphur element to the pound of body weight in adults represents a therapeutic dose. This is equivalent to 2.5 to four c. c. of solution. In acute cases one injection was given every day for six consecutive times using four c. c. (seventy-five to eighty milligrams) as an average dose; then the same dose was repeated every second or third day respectively, as clinical conditions seemed to indicate. Injections were given before noon on a fasting stomach and food was not given until two or three hours after the injection. If given upon a full stomach, chills are much more likely to occur.

Injections are given under aseptic conditions and precautions governing intravenous administration of any drug. In the writers' experience covering over six hundred injections no accident or serious reaction occurred. The safety of the intravenous administration of this drug in these physiological doses is augmented by its biogermicidal characteristics. For injections, an all glass syringe was used. The ampule was opened just before the injection; a predetermined volume of liquid was drawn into the syringe and followed by an equal amount of distilled sterilized water. The liquid in the syringe was shaken, air expelled and the liquid was slowly injected in a suitable vein. Care was taken so as not to lose any liquid in the tissues surrounding the vein; otherwise

local inflammation may set up which may last for three or four days. In such case, the trouble may be relieved by compresses of twenty-five per cent. alcohol. Miscarried injections never produced necrosis of tissues. After an injection the patient is held under observation for a short time and then allowed to go about.

(To be concluded)

THE TREATMENT OF BUBONIC PLAGUE

Charles Greene Cumston, M.D.
Geneva, Switzerland

The only treatment for a confirmed case of bubonic plague is intravenous injection of Yersin's serum, but to be of avail, serotherapy should be resorted to early, as soon as the diagnosis has been made. In epidemic centres, a suspicion of plague should cause an immediate resort to this treatment, but elsewhere, in case of doubt, it is better to inject forty to fifty c. c. of serum while awaiting the laboratory report.

The serum should invariably be given intravenously, as its absorption by the cellular tissue is slow and since Yersin's serum is more antibacterial than antitoxic, it is indispensable that it should enter the circulation quickly. The treatment should be massive and the first dose in an adult in which the process presents a serious aspect should be from eighty to one hundred c. c. In cases of medium intensity, from sixty to eighty c. c. would be sufficient. In children over six years of age from forty to fifty c. c. may be given, and in subjects four years old twenty c. c. can be injected daily without any danger.

Cases should be looked upon as severe when the temperature is 104° or over, with a large, painful bubo, and when the general phenomena from the onset are very pronounced, with torpor or delirium. Cases of medium intensity offer a temperature of between 103° and 104° F., with slightly pronounced general symptoms and a painful bubo. Benign cells are those where the temperature does not reach 102° F., with little pain in the bubo and the general symptoms mild or subsiding. In the larvate or ambulatory cases, if confirmed clinically, sixty c. c. of serum should be the initial dose and fifty c. c. if the diagnosis is doubtful, while waiting for the laboratory report. In patients in a very serious condition, in whom it is impossible to determine exactly the length of time the disease has been present, or in the pneumonic or septicemic types of the process, the initial dose should be 150 c. c. given at once, and it has been the practice of some English observers to give ten c. c. subcutaneously every hour in the interval of the intravenous injections. Treatment must be prolonged, the serum being injected in the same dose every day until the temperature falls. When it reaches 98.6° F. the injections are to be given for two more days in a somewhat smaller dose. If after the initial injection the temperature continues to rise, a second injection in the same dose is to be given a few hours later. Some patients have been given as much as 750 c. c. to 850 c. c. in one week.

Reaction may be immediate or late. The former consists—after large doses of serum—of nausea, oppression, chills, acceleration of the pulse, phenomena which indicate that the injections should be stopped, but with doses of one hundred c. c. or less they are not apt to occur. Late reactions consist of a return of the temperature to 102° to 103.5° F. after a phase of apyrexia. No serum should be given and a few hours later the characteristic phenomena of serous reaction appear, namely, joint pain, sweating, dryness of the mucosæ, urticaria or rubeola, or even hematuria or purpuric patches. These phenomena are without danger, and if necessary may be alleviated by four grams of calcium chloride or one gram of urotropin daily. If for some reason intravenous injections cannot be given, a dose of serum exceeding sixty c. c. of serum should be given subcutaneously in two different doses. Quite frequently there will be an immediate local serous reaction consisting of a mild pruriginous purpuric eruption. There is no special treatment for the bubo. Incision will hasten its evolution, but it should be done only when suppuration is thoroughly established.

AN ALUM OIL SPRAY AND EUSTACHIAN AND NASOPHARYNGEAL LARYNGEAL VAPORIZING TUBES

George Edward Barnes, M.D.
Herkimer, N. Y.

As I began practice in a neighborhood where there were many actors and singers, I stocked up with all the nose and throat sprays about which I had learned and could learn. I found that none of those sprays was at all ideal in chronic catarrhal conditions. From time to time I made up a few new sprays and tested them. In the spring of 1910 I tried to dissolve some alum in liquid petroleum. The preparation was almost thrown away because the alum had apparently not dissolved at all but it occurred to me to put some of the upper portion of clear oil into an atomizer and test it. It was astringent, altogether too astringent! I then made one dilution after another, testing each one, and finally reached a most useful spray. In order to pass this spray along to some medical friends I prepared a formula which states essentially the chief steps that I took in making the first and only batch that I have made:

Use the finest powdered ordinary alum and good thin liquid petroleum. Make up a strong stock solution of about four ounces by putting one half grain of alum into each ounce. Let this stand for one or two days to dissolve so far as possible, stirring it occasionally. Then visually estimate the amount of alum that has not dissolved and, after removing (by decanting the solution) the undissolved portion from the bottom of the receptacle, add this much more alum to the oil and let stand one or two days longer. Then the undissolved portion in the bottom is again removed and the resulting solution is the strong stock solution. Into a pint bottle put one and one half drams of this strong stock solution and fill up with plain oil. The resulting solution is the weak stock solution. Into a quart bottle put one tenth quart of this weak stock solution and fill up with plain oil. This last solution is the one for general use. I always shake the bottle before using although it may not be necessary. It is preferable to use hard rubber feed tubes in atomizers

when possible because the alum acts on brass tubes and in time makes the solution greenish.

Of course, with further investigation this formula could be simplified but, as it is already practical and provides a large quantity of solution and as I have already spent much time on it, I feel that it should be announced without further delay.

This alum oil spray is by far the best astringent spray that I know of in chronic catarrhal conditions of the nose and throat. Whenever the mucous membrane of the nasal passages is chronically thickened this spray gives much relief, contracting the tissues and diminishing the secretion. Breathing is made much freer. In case of slight infection of sinuses it may sometimes so shrink the mouths of the sinuses as to restore drainage and cure the infection. Its astringent and possibly slightly antiseptic action may sometimes be made to act directly on the mucous membrane lining the sinuses by throwing a spray or, better, a vapor into one nostril and then quickly holding the nostrils closed with the fingers and gently blowing the breath outward against the closed nostrils, the vapor being driven by the breath into the sinuses. Only gentle force should be thus used by the breath.

It should, of course, be said that this spray can-

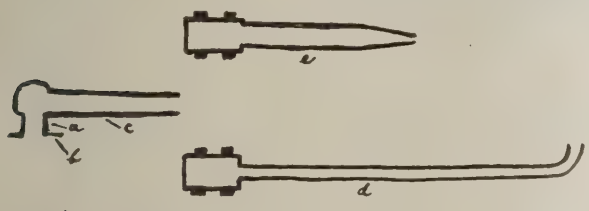

FIG.—Eustachian and nasopharyngeal-laryngeal tubes.

not take the place of operations, although it may occasionally make an operation unnecessary and alleviate cases that cannot be operated on.

Most patients who use this spray at first persistently think they should pump it into the nose from one to three times a day as they have been accustomed to do with other sprays. If they do, the conditions from which relief is sought will be made worse and the mucous membrane will become sore. It should be used only as often as the mucous membrane resumes its former swollen condition and this interval is usually several days in chronic conditions, often a week or longer. The fact that this spray needs to be used infrequently should really be one of the most valuable points about it from the practical viewpoint of the patient. Furthermore, it should be used in a very small quantity at a time lest it cause irritation, one or two actual sprays being usually enough each time. The mucous membrane of nervous people is particularly sensitive to it. In a previous article I stated that a certain emotional condition which affects the turgescence of the nasal mucous membrane is the chief cause of hypertrophic rhinitis. These cases require general treatment as well as local nasal treatment.

This spray relieves the congestion and excessive secretion of chronic pharyngitis and laryngitis. The tone of the voice is often very much improved. The throat is not so sensitive to the spray as the nose but it should not be used too often.

In acute rhinitis the spray is not so good as milder sprays, although it may be of some benefit if used cautiously in some people who are not sensitive.

One hay fever patient volunteered to try the spray but the nasal irritation was aggravated. I know of no other case of hay fever in which it has been used and I would not prescribe it for that ailment.

Acute pharyngitis and laryngitis are often well treated with the alum spray if it is used with caution.

My spray is again the best one in cases of swelling and inflammation of the eustachian tube and is possibly of value in early slight infection of the middle ear. A spray or vapor thrown against the pharyngeal end of the tube is sometimes sufficient to stop the disturbances, the tissues thereby being made to contract sufficiently to restore ventilation. A vapor from a nebulizer is best thrown into the eustachian tube by means of my eustachian vaporizing tube which connects with the eustachian catheter, although, if it is considered permissible, a vapor may be placed in the nasopharynx by my nasopharyngeal laryngeal tube and then blown into the eustachian tube and middle ear by the Valsalva method.

It is hoped that others will help to determine the exact applicability of this spray.

In order to obtain improved apparatus for using a vapor of my alum oil solution I devised several years ago special attachments and tubes, but any oil spray can be used in this apparatus.

The drawings appearing here are about half actual size. A vertical tube a, projects a short distance upward from the top b, of the bottle. To this vertical tube is attached a horizontal tube c, one and a half inches long and on this horizontal or stem tube fits either of two removable tubes, one, the nasopharyngeal laryngeal vaporizing tube d, four and a half inches long with a distal end which makes a curve and projects one quarter inch in a direction at 90 degrees to its main tube, and a second tube, the eustachian vaporizing tube e, two and a half inches long, the distal tapered end of which fits directly into the large end of the eustachian catheter. Each of these two tubes has a long doubly milled collar on the proximal end. These milled collars are easily held in the fingers and can be pushed over the slightly tapering end of the horizontal stem tube so as to make an air tight joint.

By turning the collar of the nasopharyngeal laryngeal tube its angulated end can be so directed that a vapor can be thrown in any direction at a right angle to the main tube so that it will reach the upper nasopharynx, the posterior nares, the pharyngeal ends of the eustachian tubes, and the larynx. (The other, straight tube may be used to throw a vapor on directly accessible parts.)

The eustachian vaporizing tube would be improved by being made one or two inches longer to facilitate handling. This makes a very satisfactory apparatus for throwing a vapor into the eustachian tube and even into the middle ear. It has no cumbersome length in which the vapor is wasted before reaching the tissues and there is in it no rubber tubing to become useless. As this tube is short, however, the force applied to the bulb must be gentle lest too great a volume of air be driven into the middle ear.

Historical Medicine

Kidney Physiology and Anatomy According to Hippocrates and Aristotle

JONATHAN WRIGHT, M.D.,

Pleasantville, N. Y.

For a period of two hundred years the Persian power was paramount along the shores of the Eastern Ægean and in the hinterland. As we learn from Herodotus the island of Cos suffered from its inroads, not like Cnidus and the Ionian cities of the mainland, but its influence also pervaded Cos. During this period a son of one of the priests of Æsculapius, bearing his father's name, played in the shadow of the temple walls. Along the corridors within where lay the sick, if they were lucky lapped by the tongues of dogs and visited by snakes and by Æsculapius himself in their dreams, the boy following his father may have looked up and seen the votive tablets hung in gratitude or supplication on the walls. On some of these, pinned there for instruction, there was writing in ancient script and we may imagine the boy in his school exercises spelling out the archaic words and allowing, by thus lingering over them, their meaning to sink into his consciousness.

Whether this young Hippocrates, second of the name, or a later or an earlier one wrote down the Coan mottos on a more portable palimpsest no one seems to know, but from some such one originating in some such way they have been preserved for us by eighty generations of men. It is best to read them in the ancient tongue as did the boy. He spelled out the words doubtless in a tongue that was his own, however quaint the words, lingering over them and letting his imagination sweep across the centuries from Egypt and the Ionian cities. As he grew older they mingled with his conceptions of what he saw there along the shady corridors, patients prostrated with the fevers of the Mediterranean, typhoid and typhus perhaps, but certainly malaria, doubtless of differing types, septic fever from wounds or whatever cause, pleurisies, pneumonias, acute phthisis, all classified in a way he could understand and we can not. Thus as the modern reader slowly extracts the meaning of the old Greek and tries to bring the list in line with our modern categories the mind has time to draw pictures of the scene and the scenery, remembering the chiseled figures along the brim of some old cup or the fragment of some façade rescued from the dust and mould of two thousand years and furnishing us, in our modern processes of reproduction, the material out of which we can build dimly that old life traveling along the wavering borderline of prehistoric times.

Far down the centuries from Hippocrates, Strabo (1) saw at Cos the celebrated temple, full of votive offerings and on its walls the picture of Venus emerging from the sea, not there in the time of Hippocrates and in Strabo's time to be carried away to Rome by Augustus and dedicated to Divus Julius Cæsar. Strabo tells us of the tablets and the wall inscriptions, tablets like those at Epidaurus and Tricca in Greece. These looked down in the moonlight of the pillared wards and, if not in their dreams, in their imaginations, which were then the most awake, the patients saw the shadowy forms of Æsculapius and his daughters, Ilythyia, Panacaea, Hygeia, pacing these corridors along which the to us scarcely less dim figure of Hippocrates followed his father.

Somewhere Galen says the Æsclepiadæ handing their art down from father to son, anatomy was taught to the boys as a part of their elementary education and it came to be such a matter of common knowledge in a close trade union of the art of medicine they rarely wrote of it. There is, however, a work on anatomy (2a) included in the Hippocratic Corpus, which is a fragment of a work probably antedating the birth of Hippocrates II. From this we get the information that "from the gates of the liver goes the slanting (scalene) vein down to below the kidneys." In the *II Epidemics,* which, it has been conjectured, is the work of a son of Hippocrates II, the author says two vessels (veins he calls them) starting from the clavicle, after going beneath the pleural cavity, go to the subumbilical region. "From there I do not know where they go" (2b). While it seems almost impossible this could have been written as late as the time of Aristotle it is scarcely suggestive of Galen's idea that these boys of the Æsclepiadæ could have imbibed much anatomy with their mothers' milk. If it was a son of Hippocrates II did not know and apparently did not care much what became of the abdominal aorta and the vena cava, it seems probable the child's course in anatomy was not very thorough. At any rate this must have been written a number of years before the birth of Aristotle which is supposed to have been about 334 B. C. while Hippocrates II, sometimes said to have lived a hundred years, most commonly has the date 460 B.C. given as the year of his birth.

It is, however, the quotation from the anatomy stressing the connection of the liver with the kidneys, by mentioning a direct route to it by a hollow vessel, which I wish here to keep in view. In order to develop an account of the erroneous ideas that were entertained by Hippocrates, but especially by Aristotle, as to the kidneys, it is necessary to review the gross errors of the anatomy with which they were entangled, for we shall find some even of the Galenic physiology issuing from a tendency of shading the anatomy to suit preconceived ideas of vital function, even after from Egyptian Alexandria came the light of a vastly better anatomy. While the trace is a faint one which leads back from the Hippocratic anatomy, to which I have just referred, to the Egypt before his time there seems no escape from the conviction that there was a path from the Nile across

the waters and by the land routes over which the undertaker anatomy of the Ancient Egyptian passed to the Greek.

The embalmers' anatomy is what one finds in the Papyrus Ebers. The old embalmers of Egypt, accursed of the gods and abhorred by man, were not curious whether it was air or blood or water flowed along the vessels, and even Aristotle thought it was air, at least in the artery, but let us note in this ancient Hippocratic fragment of a book of anatomy that the bronchi were not differentiated from the arteries by name and with this we are particularly struck in the Papyrus Ebers. The aorta even was only first by Aristotle given definitely the name which formerly applied to the air passages as well. In close juxtaposition in the Papyrus Ebers as in the Hippocratic Anatomy we find two vessels go to the kidneys and four to the liver. There seems reason to believe the Egyptian anatomist had in mind the "bronchi" in this connection or he would have made two vessels go to each of the kidneys, in order to include the veins. It is singular that the Greeks who did much for almost all branches of science and art and literature, when they took over the civilization of the Orient, should have done so little for anatomy until they went back with it to Alexandria. The *Praenotiones Coaci* are the origin of the *Prorrhetics* and upon them is built the superb semeiology of the Hippocratic Corpus. They have a very close affiliation in form at least with the *Cnidian Sentences*. The latter was the last word of the Orient and the Praenotiones the first word of western civilization.

Temple of Æsculapius at Cos

Ancient archeology has in later years confirmed the view long held before its rise that medicine in the Hippocratic writings had its origin in the older civilizations, but the Greeks with a magic wand seem to have touched it and freed it of magic and mysticism and converted it into a science, but they did it apparently without any benefit from morphology at the time, for there was none apparently, or very little, before Aristotle. He succeeded to the science that was open also to Plato, who declares in the *Timæus* (3): "The lung is full of holes like a sponge in order to accommodate the pneuma and the *drink* it receives." We see, therefore, before Aristotle not only structure but the functions of the conduits of the body were not differentiated.

Why Plato should have entertained this notion of primitive anatomy, if the *IV Maladies* of Hippocrates had been written and was current in the world in his time it is difficult to imagine. For in it, it is declared (2c) that such belief as that drink goes to the lungs is a mistaken opinion. Indeed this book of the Hippocratic Corpus once ascribed to Hippocrates born in 460 B.C. seems to be referring in refutation to this very passage in the authenticated late work of Plato born thirty years after Hippocrates. The author of the *IV Maladies* asserts that those who hold the opinion that drink goes to the lungs are deceived by the fact that "the lung is porous and there is a pipe going to it." In the book on the *Nature of the Bones* which is also a compilation and in many parts alien to Hippocratic thought the kidney is likened in form to a heart (2d). "They have cavities which resemble ventricles turned toward the veins, whence the veins grow out of it to the bladder. Then the water is as though filtered through the kidneys and through these same interior channels which it follows. For that which leads from them to the bladder is spongy and the urine is filtered and secreted from the blood." I follow Littré's translation for I do not pretend to understand the passage.

In a previous paragraph the author of the treatise is likewise confusing: "Drink through the pharynx and œsophagus; the larynx into the lungs and tracheal artery: from these parts to the top of the bladder." In the book *On the Heart* (2e) this seeming idea of the drink going to the lungs is only partly shared. Some of it goes along with the air but most of it goes to the belly. In all this one gets the atmosphere of the ancient Egyptian anatomy, but still we get here the inquiring mind of the Greek—the intrusion of the experimentalist. It is in this book is cited the experiment by which it is proved the drink goes to the lungs. A pig given blue colored water, his throat is cut and it is seen in the larynx. The question of the authenticity of this book, which seems a collection of anatomical notes, is too complicated for any exposition by me, but the reader can consult Littré and Adams. We see, however, it is permissible to point out there evidently was a large belief loose among the Æsclepiadæ in the fifth and sixth centuries B.C. that some at least of the fluid swallowed went into the larynx and thence more or less directly to the bladder and we shall find Aristotle looking on the bladder not alone as a reservoir but as an organ secreting the urine, the kidneys being only adjuvant to this function.

While both Littré and Adams have a high opinion of the work called *The Glands* (2f) the ancient critics apparently did not consider it highly enough to mention it as a Hippocratic book, but if Littré is right in his surmise that it is affiliated with the Cnidian School of Medicine, or on the supposition it is an early Coan treatise, we can understand the confusion about the destination of fluids and indeed there is no reason why we should not regard as among the most ancient of the books of the Corpus those in which the pulmonary route is the way chosen for them. In *The Glands* it is said: "The kidneys also have glands, for they are saturated with much water, and the glands here have more of it than gland structure elsewhere, for the water running in

is not absorbed by the kidneys, but runs through down to the bladder so that what they gain from the conduits (arteries?) this they draw to themselves," and here we find confusion worse confounded in no way elucidated by Littré's translation.

Plutarch in the *Symposiacs* of his Morals (4) makes some of his interlocutors defend the opinion they profess to find in Homer, Alcaeus and even in Euripides and Hippocrates that water passes into the lungs when swallowed, saying also that Erasistratus took the trouble to refute the opinion of Plato. Is it possible he is the author of the refutation in *IV Epidemics?* On the other hand Eratosthenes, Protagoras, Eupolus shared Plato's view. It is quite possible that in the Hippocratic Corpus as it existed in the time of Plutarch, who lived perhaps a hundred years before Galen, there was more testimony for that contention, but as we know it the assertion made in Plutarch's *Symposiacs* that Hippocrates thought of nothing else is not borne out. We see, however, that there is no reason to doubt it was primitive doctrine at the rise of Hippocratic medicine.

(*To be concluded.*)

Contributors to the Science of Medicine

CHARLES EDOUARD BROWN-SÉQUARD

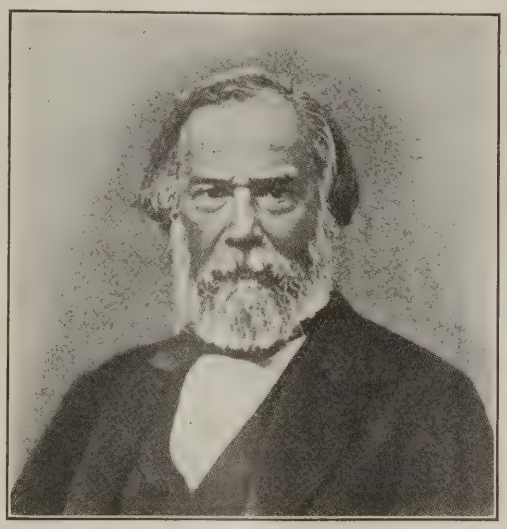
Charles Edouard Brown-Séquard has been characterized by one of his biographers as "a scientific Ulysses, who saw the manners and cities of many men." He journeyed across the Atlantic Ocean more than sixty times, never settling long in any one place. Thus the sea captain father, lost at sea several months before his son was born, lived again in him. Captain Brown was a skipper in the American Merchant Marine, sailing from Philadelphia. On one of his voyages in his square rigged sailing vessel he touched at Port Louis, chief city of the Island of Mauritius in the Indian Ocean. Mauritius was at that time one of the French colonial possessions and so had many Provençal colonists, among them the Séquard family. Captain Brown persuaded one of the charming daughters of this family to share his life as a sea rover, and it was in Port Louis that their son was born on April 8, 1817. The father had set sail for India some months previously and neither he nor his ship was ever again heard of. The mother took in sewing to support herself and her baby, peddling her work through the service of an old slave woman.

When Charles Edouard was fifteen, it was decided that he should add to the family finances through clerking in the general colonial store, which served, for lack of anything better, as a kind of club for the town's four hundred, including a number of literary lights of local renown. The young clerk soon made quite a reputation for charm of manner and intellectual accomplishments, and inspired by the admiration and encouragement of the colonial litterateurs, resolved to devote his life to poetry. He also attempted novels and plays, but there is no record of the latter's ever having been performed. These literary efforts were considered by the Port Louis critics as real masterpieces, and the youthful writer decided that he must go to Paris to seek fame and fortune, and persuaded his mother to accompany him. Both arrived at the French capital in 1838 with an introductory letter to the critic, Charles Nodier. To him the young colonial writer submitted his literary productions—and received probably the greatest shock of his life. The great critic advised him to seek elsewhere than in literature for the means of livelihood. The disillusionment was bitter, but Charles Edouard was never one to let the Fates rule him, so he decided, with as much firmness as he had taken up writing, to devote the rest of his life to medicine. He had had practically no education, so set resolutely to work on the rudiments, adopting a program for his day which he continued throughout his life—bed at eight and up again at two in the morning to study. Of his medical studies physiology interested him most, especially the laboratory side. He had made a good start, when his hand became infected from a postmortem wound and he was laid up for several months. He had hardly gone back to his work when his beloved mother died, and he was so completely overwhelmed by her loss that he gave up all work and began a life of wandering in his effort to find some solace. His friends came to his rescue, however, with good advice and funds and he was persuaded to return to Paris, where he took his medical degree in 1846. His thesis was on the reflex function of the spinal cord, a subject which continued to interest him profoundly throughout his lifetime. During these years he was very poor and lived in wretched lodgings without heat and swarming with the rabbits and guineapigs which he used in his experimental work. His food was reduced most of the time to bread and water. These early privations left marks on his rugged constitution that were never effaced.

However his Parisian life and his excellent work had brought him into contact with many of the great scientists and men of letters of the capital, and he in conjunction with some of these, including Claude Bernard and Charles Robin, organized and founded the Société de Biologie. Brown-Séquard was one of its first secretaries and throughout his life continued to take an active part in its work.

In 1852 he got into trouble on account of some of his political opinions, and found it wise to leave the country and come to the United States. He took passage to New York on a sailing vessel in order, so he declared, to have time to learn English *en voyage*. He earned his first money in this country by giving French lessons, but was soon taken up by some of the medical authorities, especially those who had studied

in France, and with them undertook a crusade for introducing experimental physiology into American medical schools. At this time he perfected and gave out for publication two of his greatest discoveries—that of the production of epilepsy consecutively to a lesion in the spinal cord of a guineapig, and that of the vasomotor function of the sympathetic nerve. The young doctor soon found out, however, that pure science did not "pay" any more in America than in France, and he was driven, to keep body and soul together, to the practise of cheap midwifery. This led to his collaboration in a work on obstetrics, which proved to be so successful that it brought him a small fortune, on the strength of which he married.



CHARLES EDOUARD BROWN-SÉQUARD

The next year he returned to France, but failing to find an opening for his work, set sail for his birthplace, the Island of Mauritius, arriving in time to cope with a cholera epidemic. The citizens of Port Louis had a gold medal struck in honor of these services to his native town.

Soon after the University of Richmond, Va., appointed him to the professorship of physiology, and he went there to take up his duties, but, finding the atmosphere uncongenial, resolved once more to try Paris, especially since the Académie des Sciences had awarded him a prize. Here he and Robin established a small laboratory, where many pupils afterward celebrated throughout Europe received their training. It was at this time that Brown-Séquard published his famous paper on the functions of the suprarenal glands in which he describes the experiments that led to his discovery of the internal secretions of glands. For several years he traveled through the British Isles demonstrating his discoveries in London, Edinburgh, Glasgow, and Dublin. This work made for him a great and permanent reputation as a physician, and led to many notable honors and positions, among them the chair of pathology of the nervous system at Harvard University. He had virtually decided to devote the rest of his life to work in the United States, when he lost his wife and the whole joy of life faded and went out for him. He returned to Paris and shut himself up in a laboratory. The next year, however, he consented to accept the position of professor of experimental physiology in the Paris Faculty of Medicine, but fell in love with another American lady, married her, and returned to New York. Here he founded the *Archives of Scientific and Practical Medicine*. In a year and a half his second wife died and he returned another time to Paris, a widower and a broken man. He spent two years wandering about France, England and Scotland, refusing meanwhile various offers of positions. Then he was married again, and at about the same time accepted the professorship of physiology at Geneva. Before he went to Switzerland, however, Claude Bernard's death left vacant the chair of experimental medicine in the Collège de France. Brown-Séquard was appointed to it in 1878, and this resulted in putting an end to his wanderings, for he spent the rest of his life in France. In 1894 he was once more left a widower, and on April 1st of that year he died. A biographer writes: "Brown-Séquard's name will live in the history of medicine as that of one of the master builders of the stately edifice of modern neurology. To him science owes the discovery of internal secretion, the application of which was the beginning of organotherapy."

One of the First Operations Performed

Augustin Thierry calls history a narration; Guizot calls it an analysis; but Michelet, the brilliant historian, considers that history should be a resurrection. Paris is full of memories, perhaps fuller of memories than any of the big cities with the exception of Rome, Naples, and Venice, although none of these can be compared in size with Paris. The French city has more of the romance of history than London, and especially of literary romance, as it must never be forgotten that Paris is on the whole the most literary centre of all time. France, too, has always been famed for her surgeons. When in England skillful surgery was unknown, Ambroise Paré was performing wonderful operations. In January, 1474, the churchyard of St. Severin, near the Boulevard St. Michel, on the other side of the Seine, was the scene of one of the first surgical operations done in France. At that time the physicians and surgeons of Paris represented to Louis XI that as several persons of consideration were then suffering from stone, colic, and other internal maladies, it would be of the greatest benefit if in order to trace the disease and discover a cure, the said physicians and surgeons were permitted to operate on a living man. The request was granted and the prisons were searched, until an archer was found suffering from the required malady, and condemned to be hanged for theft as well. He was taken to the churchyard of St. Severin, and there, with a flat tombstone for an operating table, amid a large concourse of people, the surgeons set to work. Contrary to their expectations, the patient not only survived the operation, but was pronounced cured in fifteen days' time. In consideration of the service he was pardoned and set free.

Editorial Articles

AROMATICS

Time was when noisome smells were believed to spread disease and among the more ignorant this belief is not dead. If the man in the street were asked why stenches were abolished he would answer because epidemic diseases were bred and spread by these means. Of course there is a substratum of reason in this superstition, for although filthy smells from drains and cesspools do not induce or disseminate directly the germs of contagious diseases, it is true that with bad smells there is an accumulation of filth which soaks through soil and subsoil, contaminates surface wells, so that only a typhoid or diphtheria carrier is needed to start an epidemic far and wide, and typhus fever, always known as a filth disease indirectly, as it is carried by lice which are only harbored by dirty persons in whom strong personal odors prevail.

The study of smells in fact is highly interesting and there has been published recently a book on smells written by a well known laryngologist of London, which it is no misnomer to state is fascinating. Dr. Dan McKenzie in *Aromatics and the Soul* has put the facts with regard to smells contained in the book in an instructive and intriguing manner. He points out that the objection to nasty odors is an outcome of that refinement of feeling which accompanies a high state of civilization. The greater the culture the greater the increase in the delicacy of the senses. The sense of disgust is heightened in men and women who strive after refinement. There is naturally a close and intimate connection between the sense of smell and the nerve centres, which, when stimulated, evoke the feeling of nausea in the mind, and the bodily acts that follow. It is nature's mode for preventing the ingestion of evil smelling things. But attention is drawn to the point that like all other nerve reactions this particular reflex can be educated, one way or the other. It can be blunted or degraded, or it can be rendered more acute, more prompt to react. Now one of the effects of civilized life, of town life, is to cut short the period of all reflex action. However, while it appears to be true that the sense of disgust aroused by unpleasant smells has come in with ultracivilization it is somewhat extraordinary to recall that it is only comparatively recently that modern civilized countries have put their houses in order in this direction. Great Britain has been the pioneer and yet up to the beginning of the nineteenth century London, according to G. V. Poore, a great authority, or paved only with rough cobblestones. There were or paved only with rough cobble stones. There were no sidewalks. The houses projected over the roadway and were unprovided with rainwater gutters, and during a shower rain fell from the roofs into the middle of the streets. These streets were filthy from constant contributions of slops and ordure from animals and human beings. There were no underground drains, and the soil of the town was soaked with the filth of centuries. This sodden condition of the soil must have affected the wells to a greater or less extent.

The nineteenth century was well on its way before the last of the private cesspools disappeared from the dwelling houses of London. As was London, so were cities in all parts of the world including this country, they one and all simply reeked with stenches of various and diverse kinds. And yet the people of that time, the higher classes at least, were fully as cultured as those of the present time, in some ways more so, although now culture is more widely diffused. Egypt, Rome and Greece, at the height of their glory, were as cultured as the present inhabitants of civilized countries and they were a cleanly people to whom obnoxious smells were abhorrent. Thus it is doubtless true that culture and delicacy of smell go hand in hand.

As for personal smells, each race has its own peculiar odor and a keen nosed man of one race can detect the nationality of a member of another race by his bodily odor. For example the Chinese and Japanese find the immediate neighborhood of Europeans highly objectionable and the Europeans return the compliment. The emanations from the skin of the negro are offensive to the white man and it is said the negro has a distaste to the smell of the Caucasian.

Perhaps the part of Dr. McKenzie's book which will appeal most strongly to the medical reader is that which discusses the especial odors pertaining to certain diseases. As is pointed out, to the keen-sensed medical man certain morbid states can be recognized by their exhalations. The author has even heard of an enthusiast on the subject who alluded to them as "both visible and tangible" but he thinks this must be exceptional.

Physicians of the last generation used to speak of typhus fever as having a close, mawkish odor, and the smell of smallpox is horrible. But these, as well as the appalling stench of the hospitals in olden days, both in Great Britain and in America, are among the smells which for the most part, have fled.

There are others, however, less powerful and repugnant, which are still with us, and which we recognize as among the prominent characteristics of some maladies, the acid smell of acute rheumatism for one, and McKenzie has sometimes thought he could detect a characteristic odor also in acute nephritis, a smell resembling that of chaff. The odor of a big hemorrhage is unmistakable and, to obstetricians particularly, ominous. Then there is the smell of mice which attends upon the skin disease known as favus. The breath of a chronic drunkard is familiar enough to everybody, and the more delicate aroma in the circumambient atmosphere of the careful tippler, ethereal and by no means unpleasant, will often reveal to the physician the hidden cause of obscure symptoms. It is particularly valuable when your patient is, as many of these secret drinkers are, a woman, it may be a woman of good social standing. A disease odor of great value and significance is the sweet smelling breath caused by acetone poisoning in the later stages of diabetes. Bacon says that a sweet smell attends the plague.

The author does not mention the unpleasant odor coming from those who are afflicted with long standing intestinal stasis. The odor in some of these cases is very pronounced.

With respect to the part played by olfaction in sex life which is undoubtedly prominent in the mating for four footed animals, McKenzie thinks that the reasoning that this is a strong argument in favor of its potency in mankind also, is fallacious. Havelock Ellis made an exhaustive inquiry into this matter and decided that the attraction, subtle as it is, is seldom or never obviously olfactory. On the other hand, although this is not referred to in the book, man in his primitive state was like the animals, but to lesser extent, lured by the scent of the female at certain periods. He has evolved from this state or nearly wholly so. There are those who hold that the olfactory lure in some instances still wields its power.

IS NUISANCE PREVENTION PUBLIC HEALTH WORK?

This is the question put by Dr. Charles Chapin, superintendent of health of Providence, in a controversial article in the *American Journal of Public Health*. Dr. Chapin opens his argument by stating that few municipal health departments do enough for public health, and that the chief reason for this is lack of money. He goes on to distinguish between public comfort and public health and asserts that in many places the terms are synonymous. "It seems to me," he writes, "that the health department, in the end, can only stand true before the public and compete with other departments in the construction of the budget, if it devotes its money and energy to the prevention of disease. Because a certain thing may indirectly or as a secondary effect influence public health, is not a valid reason for inflicting it on the health department. A wise tariff, an efficient trolley service, a sound currency, cheap coal, honest advertising, and the enforcement of the Volstead Act, would undoubtedly influence health. But no one expects the health department to secure these blessings."

He concedes that the abatement of some very flagrant nuisances clearly saves lives, but finds that the health reports of many cities show that the nuisances receiving attention relate to untidy yards, alleys, dumps, vacant lots, cellars, etc. Others relate to the handling and disposal of garbage, to stables and pigpens, defective plumbing and drains, and many other disagreeable things that "rarely have a direct bearing on health." He considers "one of the most farfetched, useless, and time consuming developments of the old nuisance idea is clean up week." Such a week, he says, consumes about two months of the health department's time and much money. Another argument against nuisance abatement by the health department is the energy consumed. He recommends that such work be done by the police department, leaving the health officer free to devote all his time and money to saving life.

"Nuisance inspection keeps alive the spirit of the filth theory. The public still believes that all dirt is dangerous. It is sad to note that not a little of the much vaunted public health education of today is contaminated by this theory. Many a cartoon pictures devilish germs emerging from a garbage can or perched on a dunghill. Many a catchy phrase in the weekly bulletin teaches that any dirt is dangerous, and that odors are deadly. Let us discharge our professional propagandist and ever stand at the shoulder of the health cartoonist. Then, when we are teaching only the truth, let us fit our practice to our teaching and give up chasing bad odors under the guise of protecting public health."

There is no doubt that much of what Chapin writes is true. But there is another side of the problem to which he does not give due consideration—the psychological side. He forgets that public health work is still in its infancy, especially in the small towns and in rural districts. The general public has to be taught chiefly through the outward and visible sign to perceive later causes and results. Hence, clean up week. It would be the height of folly to undo what has been done in the way of arousing general interest by telling people that a great many of the things they have been doing to clean up their towns are really of no value. And are they really of no value? Surely the esthetic plays a large part

in the lives of most of us, and should play a much larger. "A dead cat," as Dr. Chapin states, "will not cause diphtheria"; but who wants to keep one? "A burning dump will not affect health"; but it is certainly most unsightly and offensive. "Garbage in the ash heap never results in typhoid fever"; but it is filthy and a breeding place of disease carrying vermin. "An uncovered cesspool is a cause of death only by drowning"; perhaps, but what neighborhood enjoys having one in their midst? True, all such things can be "seen by anyone," as Chapin argues, and certainly by the police; but has "anyone," or even the police, the necessary training to distinguish between the merely obnoxious nuisance and that which is a real menace to public health?

THE HEALTH OF SCHOOL CHILDREN

The child is father of the man and the health of the rising generation is a fair criterion of the future of a country. In order that children may be physically and mentally healthy, it is essential that they be well fed, not overfed but fed in moderation on suitable diet, properly housed and clad, and allowed opportunities for exercise in the open air. Also their school life must be followed in healthy surroundings. This may seem difficult in the slums of cities like New York and London, but much can be done. Evidence of this is afforded by the annual report of the Chief Medical Officer of Health of the Board of Education of England and Wales for 1922, dealing with the health of the school child. The report, on the whole, is distinctly encouraging. Sir George Newman, the chief medical officer of health, points out that the unparalleled conditions of unemployment and financial restriction prevailing in England have not had the harmful effect on child life which might have been imagined. In fact, he considers that the pause which the need for economy has imposed in the expansion of school medical work may be looked upon as a not unmixed disadvantage. However, the report lays emphasis on the gross inequalities which exist between various areas and lays urgent stress on the fact that a minimum standard is needed for all districts.

The most pressing questions awaiting solution are the following: The further coordination of the school medical work with the public health service; the physical condition of children under five years of age; the effective education of the dull or backward child; the importance of a comprehensive scheme for the treatment of dental defects; and the systematic organization of the teaching of hygiene and physical training. As for the care of children under five years of age, the report goes on to say, it may be safely assumed that from eighty to ninety per cent. of children are born healthy and with the potentiality of leading healthy lives. Whatever be the facts of parentage, the tendency of nature is to reassert the right of each new generation to the heritage of a healthy birth. The report further points out that after the first year of life the young child has to bear a heavy burden of environmental neglect associated with bad housing, poverty, and absence of hygienic supervision. As a result, the school medical service is faced with the hard issue, that out of an infant population born healthy, thirty-five to forty per cent. of the children admitted to school at five years of age bear with them physical defects which could have been prevented. The report asserts that attention in preschool days would give children a reasonable opportunity for proper education and would produce a great saving in subsequent medical supervision. It regrets that the institution of nursery schools has had to be curtailed.

The findings of medical inspection are summarized thus. Routine medical inspection finds that about forty per cent. of the children have a greater or less degree of physical defect. Definite malnutrition, heart disease, anemia, and deformities are each present in about two per cent. of the children. A larger burden of disease consists of: defective vision, twenty per cent.; ear, nose and throat diseases, fourteen per cent.; and a severe degree of dental disease, thirty-four per cent.

Secondary schools in England and Wales were examined last year. In the main the biggest number of defects were in the same proportion as in the elementary schools, but the fourth in the numerical list is deformities. The report referred to and quoted from is extremely valuable for purposes of comparison. In all civilized countries the condition of the children in the large cities have many features in common. The condition of English children is probably worse than that of other civilized countries because the population of England is mainly in towns and because England has been an industrial country longer than any other. But while such is the case, there are many industrial cities of this country where the conditions of life in the tenement districts rival, perhaps, in overcrowding and squalor any which may be found in England. The hopeful note which has pervaded the reports of the chief medical officer of the English Education Board shows that the efforts to improve the health of children have borne good fruit. The welfare workers and the medical department of the Education Board have already reaped a satisfactory harvest in return for their labors and the auguries are that their success in the future will be greater. What is most needed now in all great cities is that home environment should be improved. Unhygienic houses should be destroyed and replaced by roomy and well ventilated houses.

FOOD POISONING

On account of the large increase in recent years in the number of fatal cases from food poisoning, several of the leading public health journals have been printing warnings against certain types of food the consumption of which may lead to such poisoning. One of the best discussions of the subject forms the leading editorial in a recent issue of the *Monthly Bulletin* of the Boston Health Department. The writer, Francis H. Mahoney, Health Commissioner, believes that one of the reasons for this increase in cases of food poisoning is the fact that the war and the high prices left in its wake created a habit of conserving food sometimes not fit to eat. "A great deal of that which formerly went into garbage receptacles," he writes, "now find its way, in one form or another, into human stomachs."

One method of food poisoning is from contamination with mineral poisons resulting from the chemical action of certain foods on their containers. The habitual taking of copper salts may have a relation to the production of cirrhosis of the liver. The extensive use of arsenate of lead and poisonous solutions in spraying trees and crops sometimes results in making their products dangerous for consumption. Anaphylaxis, or protein sensitivity to certain kinds of food, often causes symptoms of food poisoning. These are gastrointestinal disorders, with or without urticaria, eczema, and nervous affections, such as migraine. Skin tests may help to confirm or discredit suspicion of anaphylaxis.

Qualities inherent in or acquired by foodstuffs may cause poisoning, for example mushroom poisoning and poisoning from cow's milk when the animal has eaten something of a contaminating nature. Food may also be contaminated by bacteria of certain types. Some of these do not produce symptoms of poisoning until after they have been introduced into the body and become active; others by their growth and activity in the food before it is eaten produce toxins which themselves cause poisoning when they are taken into the body with the food, irrespective of what the bacteria may themselves be capable of doing after entering the body. Most of the bacteria that produce food poisoning belong to the colon typhoid group. They include the Bacillus enteritidis, the Bacillus choleræ suis, the socalled hog cholera bacillus, and the paratyphoid bacillus. When food contaminated with these organisms is eaten, they cause in susceptible cases pronounced gastrointestinal disturbances, now regarded as frequently the result of the patient's being infected with the bacilli themselves, rather than the result of any "ptomaine" taken in with the food. That is, such symptoms are similar to those of the infection of a susceptible person with an acute infective disease.

One of the most serious, and of late one of the most frequent, forms of food poisoning is through the bacillus botulinus. The natural habitat of this bacillus is, like that of the tetanus, in the soil, preferably new soil. Also like the tetanus bacillus, it is harmful to man and animals only accidentally and under certain peculiar conditions. These dangerous possibilities manifest themselves chiefly through the effects of a toxin on the nervous system. The bacillus botulinus owes its name, which means the sausage bacillus, to the fact that it was first identified in connection with poisoning from eating sausages. The source of the bacilli was the imperfectly cleaned intestines of herbiverous animals of which the sausage skins were made. This bacillus is spore bearing and the spores are extremely resistant to heat. It is widespread in its distribution and likely to poison foodstuffs that may come in contact with the ground. A few years ago it achieved prominence by a number of deaths caused by eating canned ripe olives and spinach. Since then it has been found in home canned foodstuffs. It has caused also wholesale deaths of livestock that have eaten alfalfa in certain localities. Boiling thoroughly for forty minutes destroys the toxicity, but it takes at least six hours' boiling, and a higher temperature, if possible, to destroy the spores.

SOCIAL WORKERS AND VENEREAL DISEASE CLINICS

In a recent issue of *Health and Empire,* the official publication of the British National Council for Combating Venereal Diseases, Dorothy C. Hare, M.B., C.B.E., contributes a valuable discussion of the functions of social workers in connection with venereal disease clinics. The Trevethin Committee has recommended the employment of trained social workers on the staffs of clinics to teach patients and to give general advice and assistance when required in the following paragraph:

> As it is agreed that it is essential for the prevention of disease that there should be widespread knowledge among the community of the nature and consequences of these diseases, it follows that the importance of giving repeated personal instruction and warning to patients attending the clinics cannot be overstated. We think that this duty must always devolve mainly on the doctors, but that it might well be supplemented by trained social workers who for this purpose and that of giving advice and assistance should be attached to the staff of a clinic.

The writer discusses the various questions involved in such a step—theory, practice, and methods. The objection that the bond of secrecy under which the clinic works would be violated by the introduction of a social worker is answered by the fact that

the teaching, although individual, may be and should remain impersonal unless or until a personal application is given it by the patient and personal advice asked. Most patients will be just as desirous of protecting members of their families from infection and of knowing how to do it as patients suffering from other infectious diseases, and those medical officers of clinics that spend most of their time teaching their patients will be very ready to welcome assistance in the work. The time and energy of the doctor are limited, and his first duty is treatment, not instruction.

> Patients may be stupid or careless, and nothing but repeated telling will reach their understanding. More often they are ignorant and contending with circumstances under which the necessary steps to be taken to avoid the transfer of an infection and the carrying out of treatment are very difficult. From such the more leisured teacher will probably draw questions and a spontaneous request for advice.

In discussing methods of application of the principle, two questions are involved: How shall it be done, and by what type of persons? The latter involves the most important factor in the success of the work. The committee recommends the *trained* social worker. The task requires technical knowledge, knowledge of human nature, experience, and tact. "The worker must appreciate the difference between the precepts of health and of morality, and must be bound over to teach only the former when on duty in the clinic, and to refrain from inquiries of a personal nature, though showing a willingness to listen. Many patients will spontaneously present their personal difficulties to a sympathetic ear if these confidences are not directly sought." The worker and patient should be of the same sex.

The method of instruction will vary with the teacher, but it is suggested that the text of the teaching should be a printed paper which in all clinics is handed to the patient on first attendance. To read this through with the patient, underlining verbally the most important sentences, affords a good opening for discussion and question, or, if these are not forthcoming, the reading in itself is valuable. The worker should have some other function in the routine of the clinic which brings him or her into contact with all patients automatically, so that at later visits the acquaintance begun can be improved and further opportunities for instruction arise, perhaps on a hint from the doctor. Throughout, the advice of the doctor is necessary, and close cooperation with him, for successful work. "It is particularly necessary to combat the belief that circulates widely that negative reports, whether of blood reactions or films, mean a cure, and that from that day no further attendances are necessary. If this can be successfully done, a certain percentage of defaulting will be prevented." The scope of the work is probably wider for women than for men. The mother of a family who is infected or who has an infected child, or the young girl, must be instructed, not only in how to avoid infecting others, but often in difficult problems of bad housing conditions, occupation, and pregnancy. The child with gonorrhea is one of the greatest difficulties of the clinics, not only in regard to lengthy and difficult treatment, but also as to regular attendance at the clinics, and prevention of spread of infection. Domestic servants are particularly hampered in availing themselves of treatment. The work of following up defaulting patients by friendly letters could also devolve upon the social worker. In fact, in helping to solve or at least to mitigate the conditions involved in all of the above types of problems, the social worker's assistance would be invaluable *per se,* and could also be made exceedingly helpful to the physician, not only in saving his time and energy, but in carrying out his instructions.

BARRO COLORADO ISLAND RESEARCH LABORATORY

So much interest has been evinced by our readers in that portion of our Latin America news letters which refer to the opportunities for biological research in the tropics, that we have asked our Latin America correspondent to contribute a special article on the Barro Colorado Island Research Laboratory. The outlook of medicine has been so broadened in recent years that the physician and surgeon of today takes a greater interest than ever before in the progress which is being made in the allied branches of science. The location of the Barro Colorado Island in the centre of the Panama Canal Zone, makes it a place which is easy of access by all scientists: more than this, it affords a peculiar interest to every American who takes a patriotic pride in that greatest of all human accomplishments, The Panama Canal.

News Items

Speech Disorders.—The National Society for the Study and Correction of Speech Disorders will hold its annual meeting in Washington on July 4th and 5th.

Medical Unit Reviewed.—Surgeon General Ireland reviewed the 102d Medical Regiment of the New York National Guard at the state military camp at Peekskill.

National Board of Medical Examiners.—Examinations of students in Class A medical colleges were held in thirty-three cities and three R. O. T. C. Army Camps, June 19th to 21st.

Princeton Infirmary.—The cornerstone has been laid for the new infirmary at Princeton University, to be called the Isabella McCosh Infirmary, in memory of the wife of former President McCosh.

American Physicians Go to Vienna for Postgraduate Study.—Under the leadership of Dr. G. W. Mackenzie, of Philadelphia, fifty-two physicians from all parts of the country have sailed for Vienna for postgraduate work in otolaryngology.

Change in Name of Medical Journal.—*California and Western Medicine* is the new name of the *California State Journal of Medicine,* the official organ of the California, Nevada and Utah state medical associations.

Scientific Congress.—The third Pan-American Scientific Congress will be held at Lima, Peru, for two weeks, beginning November 16th. There are to be sections on medicine and sanitation and on biology and related sciences.

Infantile Paralysis Study.—Dr. Milton J. Rosenau, of Harvard, is studying the nature of the infantile paralysis bacillus, for which a grant of $12,000 a year for three years has been made by the Harvard Infantile Paralysis Commission.

Southern Physician Honored.—In recognition of the forty years' practice of Dr. Roger A. Mallory, in the small town of Concord, Georgia, its entire population held an old fashioned southern barbecue, attended also by about twenty-five physicians from the vicinity.

Shortage of Nurses.—A special meeting of the Philadelphia County Medical Association was recently called to consider the shortage of nurses. Dr. S. Lewis Ziegler of the society is chairman of a committee which has been making a six months' study of the subject.

Prize Essay Contest.—A prize of three hundred dollars is offered by the Fiske Fund of the Rhode Island Medical Society for the best essay on Recent Progress in Plastic Surgery. The winner of the 1923 contest, on the subject of treatment of neurosyphilis, was Dr. James Lincoln McCartney, Washington, D. C.

Buffalo Academy of Medicine.—Dr. Thew Wright, one of the two candidates for president of the Buffalo Academy of Medicine in a tie vote, withdrew his name for what he pronounced "the best interests of the Academy," to avoid the necessity of a special election. Dr. George R. Critchlow was then declared elected.

Training in Child Care.—A statewide campaign is being undertaken in Wisconsin to teach school girls how to care for little children. The work is under the direction of the State Board of Health and Vocational Education and the State Department of Public Instruction, with a fulltime organizer.

Philadelphia Medical Charity.—Fully half of the expenditures of 1923 for welfare activities in Philadelphia were devoted to medical charity, according to figures recently issued by the All Philadelphia Conference on Social Work. Hospitals and dispensaries received $10,662,000; extra institutional health service and sanitation, $1,251,000; physically handicapped, $776,000, and mental health, $2,716,000.

Research Prize.—In commemoration of Dr. Charles Lester Leonard, a martyr to the x ray, a prize of one thousand dollars has been offered by the American Röntgen Ray Society for the best piece of original research in the field of the röntgen ray, radium, or radioactivity. Papers are to be submitted not later than May 1, 1925, to Dr. George W. Grier, 8088 Jenkins Arcade, Pittsburgh, who is chairman of the committee.

Infant Mortality.—According to the annual report of the board of health of Hawaii, the infant mortality rate for the year ending June 30, 1923, was 139.92. Analysis of the figures showed a variation from 55.67 among the Caucasians, to 366.15 among the Filipinos. The Chicago Infant Welfare Society has found that the death rate among the eleven thousand babies it cares for is only one fourth that of the general infant death rate in the United States. Almost half the number of deaths among the children it cares for are due to respiratory infections, dependent to a large degree on general health measures.

Personals.—Dr. Frank Billings, of Chicago, has received the honorary degree of LL.D. from the University of Cincinnati.

Dr. Robert F. Sheehan has been appointed manager of the new Harlem Valley State Hospital, at Wingdale, New York.

Dr. Henry H. Forbes, professor of laryngology of the New York Post-Graduate Medical School, has gone to Europe to visit the Laryngological Clinics of Paris and the clinics of Professor Mourè in Bordeaux.

Dr. Herbert Acuff, of Knoxville, Tennessee, has been elected president of the Chamber of Commerce.

Medical Relief.—The sum of eight thousand dollars was expended during the year by the Association for the Relief of Needy Physicians of Central and Eastern Europe, according to its report of May 22, 1924.

Better Baby Conferences.—The state department of health of Illinois is arranging for thirty-two better baby conferences, to take place mainly in connection with the various county fairs.

Maryland Appropriations for Care of Insane.—The amount of $667,000 has been appropriated by the Maryland legislature for the state hospitals for insane and feebleminded patients. New buildings will be erected at all the state hospitals.

Hospital Changes Location.—The Samaritan Hospital of Brooklyn will sell its Bay Ridge property and locate permanently at the former Skene Sanitarium, President Street, Brooklyn. The medical staff recently held a meeting at the Brooklyn Chamber of Commerce, to celebrate the acquisition of this new property.

Hospital Campaign.—As the result of a week's canvassing by fifteen hundred volunteer workers, the Beth Israel Hospital of Newark has received pledges amounting to $1,853,000. The figure worked for is $2,000,000. The entire hospital is to be moved to new buildings on Lyons Avenue.

State Medical Society Meetings.—The Medical Society of New Jersey recently held its one hundred and fifty-eighth annual meeting. The following officers were elected: President, Dr. Alexander MacAlister, of Camden; vice-presidents, Dr. Archibald Mercer, of Newark, Dr. Lucius F. Donahue, of Bayonne, and Dr. James S. Green, of Elizabeth; corresponding secretary, Dr. William J. Carrington, of Atlantic City; recording secretary, Dr. John Bennett Morrison, of Newark; and treasurer, Dr. Elias J. Marsh, of Paterson.

The Rhode Island Medical Society has elected the following officers: President, Dr. William F. Barry, of Woonsocket; vice-presidents, Dr. Halsey DeWolf and Dr. Herbert G. Partridge, of Providence; treasurer, Dr. Jesse E. Mowry, of Providence; and secretary, Dr. James W. Leech, of Providence.

The Oregon State Medical Association has elected the following officers: Dr. Alfred C. Kinney, Astoria; president-elect, Dr. Paul F. Rockey, of Portland; vice-presidents, Dr. Ralph Fenton, of Portland, Dr. Leo B. Bouvy, of La Grande, and Dr. George E. Dix, of Marshfield; secretary, Dr. Courtland L. Booth; and treasurer, Dr. Ralph C. Walker, of Portland.

National Association Meetings.—The American Laryngolical, Rhinological and Otological Society has elected the following officers: President, Dr. William H. Haskin, New York; vice-presidents, Dr. Gordon Berry, Worcester, Massachusetts, Dr. Hugh M. Taylor, Jacksonville, Florida, Dr. George F. Keiper, Lafayette, Indiana, Dr. Don A. Vanderhoff, Colorado Springs, Colorado, and Dr. Edward C. Sewall, San Francisco; secretary, Dr. Robert L. Loughran, New York, and treasurer, Dr. Ewing W. Day, Pittsburgh.

The American Association of Genitourinary Surgeons has elected the following officers: President, Dr. Arthur L. Chute, Boston; vice-president, Dr. William F. Braasch, Rochester, Minnesota; and secretary-treasurer, Dr. Henry G. Bugbee, New York.

The National Tuberculosis Association has elected the following officers: President, Dr. Charles J. Hatfield, Philadelphia; honorary vice-president, Col. George E. Bushnell, U. S. Army, retired, Pasadena, California; vice-presidents, Dr. Walter Jarvis Barlow, Los Angeles, and Dr. Hoyt E. Dearholt, Milwaukee; secretary, Dr. George M. Kober, Washington, D. C. Dr. William H. Welch, Baltimore, Dr. Vincent Y. Bowditch, Boston, and Dr. Edward O. Otis, of Boston, were elected honorary members of the association.

The Association of American Teachers of Diseases of Children has elected Dr. Julius H. Hess, of Chicago, president, and Dr. Paul W. Emerson, Boston, secretary.

The following officers of the American Sanatorium Association were elected at its annual meeting: President, Dr. F. M. Pottenger, Monrovia, California; vice-president, Dr. David Lyman, Wallingford, Connecticut; and secretary-treasurer, Mr. W. L. Rathbun, Cassadaga, New York.

The Barro Colorado Island Research Laboratory

W. C. RUCKER, M.D.,
New Orleans, La.
Surgeon, U. S. Public Health Service

When Balboa made his famous transcontinental journey of discovery, the Isthmus of Panama was a thickly populated region. He left the shores of the Caribbean with 101 men, and in his journey to and from the Pacific Ocean, a journey which occupied more than three months, he was able to live off of the country. His men suffered none of the major diseases, and when he returned he had his full quota of men with him. It is extremely doubtful if such a feat could be accomplished today. Where once were thriving villages and farms, there are stretches of unbroken jungle. Anyone attempting to repeat Balboa's journey today would be likely to lose a considerable number of men from that malignant form of malaria known as Chagres fever, unless he was careful to administer daily prophylactic doses of quinine. But if he was an observing scientist he would have an unexcelled opportunity to study the flora and fauna of this region in an untouched state.

In the days which followed Balboa's expedition, tyranny, oppression and disease almost depopulated the area over which Balboa and his intrepid band traveled. He blazed the trail for an international highway which, after the disastrous efforts of the French and the successful endeavors of the North Americans, has now become a waterway for all the world. In the building of the Panama Canal a dam was erected at Gatun, and the waters of the Chagres River became Gatun Lake, the rising waters slowly inundating all lands above the eighty-five foot contour above sea level. Barro Colorado Island which formerly had been a large hill, was thus formed in the centre of an extensive area, which the rising waters slowly covered. Animals migrated to this island in advance of the gradually rising lake, and thus it became a refuge for practically every animal species in this district. It has remained practically undisturbed throughout the centuries and is now a virgin tropical forest in which the "balance of nature" is unmolested by human agency.

Fig. 1.—The worker at Barro Colorado Island finds much to interest him. Dr. Thomas Barbour, of the Museum of Comparative Zoology of Harvard University, and Mr. W. C. Brookes of the Boston Society of Natural History, are here shown with a large boa constrictor. At their feet is a three-toed anteater, *tomanduar tetradactyla chiringuensis allen*, which lives on the white ants or *termitis*. (Photograph by James Zetek).

The Island is situated in Gatun Lake, west of Frijoles, C. Z., with its west side bordering upon the Panama Canal prism through which pass daily the ships of all nations, bearing the representatives and the products of all peoples. It is approximately ten miles from Gatun and Gamboa, and covers about six square miles, being three and one half miles in each of its greatest diameters. Its shores are about eighty-five feet above sea level, and it reaches an elevation of 537 feet; completely wooded, excepting for a few hectares under cultivation on the southern shore, it is practically a virgin tropical forest. The number of species of plants thereon, exclusive of cryptograms, is about two thousand. Vertebrates are well represented, and opossum, sloths, anteaters, armadillos, peccary, deer, tapir, olingo, many species of rodents, tayra, agouti, squirrel, rabbits, raccoon, jaguars, pacas, coati, ocelot, bats, nightmonkeys, howling monkeys, whitethroated capuchin monkeys, spider monkeys, and other species typical of the humid lower tropical sun abound.

Barro Colorado Island thus presents wonderful opportunities, probably unexcelled in all the world, for research in biology, zoology, entomology and botany. Furthermore, it is well situated in the tropics, and is easily reached from all parts of the world. It is close enough to civilization, so that all of the necessities of civilized existence may be readily secured. Specimens may be easily shipped —in fact, it is the ideal location for a research laboratory. The project of the creation of such an institution was thoroughly considered by Dr. William Morton Wheeler, dean of Bussey Institution; Dr. Richard P. Strong, director of the School of Tropical Medicine of Harvard University; Prof. Charles C. Piper, agrostologist, U. S. Department of Agriculture, and Mr. James Zetek, specialist in tropical entomology, Bureau of Entomology, U. S.

Department of Agriculture, and on March 27, 1923, was presented to the Governor of the Panama Canal, Colonel J. J. Morrow, U. S. A. (retired). Under date of April 17, 1923, he set aside this Island as a natural park, and prohibited all hunting thereon. At once work was begun on a laboratory building. This is now completed, and consists of a well screened airy building, thirty-two by fifty-five feet, with a ten-foot screened veranda. It is equipped with excellent beds, kitchen equipment and dining room gear. There are shower baths and toilet facilities—in fact, everything which is necessary has been provided to carry on scientific research comfortably. The material for research is at the very door of the laboratory, and the scientist has only to walk a few feet into the jungle where something of scientific interest is happening every moment.

In previous letters the opportunity for studying ants, mosquitoes, other dipteras, bees, snakes, lizards, frogs, toads, mammals, and birds, have been dilated upon. The only thing necessary to round out the biological studies which may be made in this region, is a moving biological laboratory, and it is planned to create one in connection with the Gorgas Memorial Institute at Panama. In the regions easily reached from Barro Colorado Island, there is an opportunity for studying life in the arid lower tropical zone—in fact, from this point it is possible to make biological studies in every zone, from the humid lower tropical zone to the temperate zone.

FIG. 2.—The broad sabanas are frequently punctuated by the nests of the white ants, *amintermes medius*. They are grayish white in color, and almost as hard as stone. Frequently they are so thick that the field looks as though it were covered with Indian tepees. The one here shown is only medium sized. (Photograph by James Zetek).

FIG. 3.—Barro Colorado Island as here shown is in the centre of Gatun Lake, and before it runs the pathway of the world's shipping.

Contributions are being received for the expansion and continuance of the operations of Barro Colorado Island, and the chairman of the Executive Committee of the Institute for Research in Tropical America, whose address is, The National Research Council, Washington, D. C., will gladly receive any such. This article is not intended as a plea for these contributions, but it is felt that this is a matter of such importance and interest, that it would be lacking if the above information were not given.

The universities, museums, scientific societies and similar institutions of North America are sending workers to the Barro Colorado Island Research Laboratory, and it is believed that it will be possible here, not only to add greatly to the sum of human knowledge in the direction of pure science, but also to gain information which will be of the greatest practical value in the conquest of the tropics.

Foreign Correspondence

LONDON LETTER

(*From our own correspondent*)

LONDON, *May 20, 1924.*

CAUSES OF A C3 POPULATION

Dean Inge presided the other evening at a Chadwick public lecture given by Professor MacBride at the Royal Society of Arts, London. He said that the welfare of a nation did not depend on the amount of its imports or exports, but on the quality of the men and women composing it. The quality of a population depended partly on heredity and partly on environment. The importance of environment had been stressed, while the influence of heredity was neglected. Some people said that to study heredity was absurd, others said that it was contrary to religion, while some said that its effects were known already to all. Nowhere could they find recognition of the truth so uncompromising as in the Scriptures. "Do men gather grapes of thorns or figs of thistles?" If these words did not attach importance to the problem of heredity he did not know what words meant. He thought it was ridiculous to say there was anything contrary to the principles of Christianity in the study of the problems which Professor MacBride had investigated. Professor MacBride defined the phrase "C3 population" as a term to denote the physically and mentally deficient; C3 men were not "throwbacks" but products of imperfect development. The question of whether mental de-

ficiency was inherited had been settled in the affirmative by the researches of Dr. Goddard, an American, who had found that of 482 children of mentally defective parents whom he had examined 476 were defective. A C3 population was largely the result of reckless and improvident reproduction, the only remedy for which was in rigid birth control and eventual sterilization of the unfit.

The lecture referred to Terner's studies of goldfish, all the fancy breeds of which had been produced by the Chinese breeders from a grey carp by interbreeding monsters which were in turn produced by rearing the fish in water which was deficient in light and oxygen and was otherwise unsanitary, and his studies of frogs. His experiments, which were confirmed by a Dutchman, Dr. Jansen, tended to show that C3 human aberrations had a similar cause. Natural selection was the broom by means of which Nature kept other races of animals healthy and clean. If we interfered with its operation in the case of man, we must replace it with some other kind of selection, otherwise we should always be troubled with a "C3" population. Modern philanthropy by endeavoring to keep alive all children, however feeble, had only increased the evil.

NEW LABORATORIES AT CAMBRIDGE UNIVERSITY

Lord Balfour, as Chancellor of Cambridge University, opened on May 8th last the new Sir William Dunn Laboratories. These are a valuable addition to the resources of Cambridge University, making possible for the first time the concentration of the School of Biochemistry within one well equipped and thoroughly up to date building. The laboratories which are situated opposite Pembroke College were built by money left by Sir William Dunn for the "alleviation of human suffering" and which his trustees decided should be devoted to biochemistry. The executors recommended that out of his estate £210,000 should be set aside for this purpose. The actual building has cost about £96,000 and the laboratories are fully equipped. They were formally handed over to Lord Balfour.

Lord Balfour in his speech asked what could biochemistry do for mankind, which chemistry, especially organic chemistry, was not qualified to do already. He pointed out that biochemistry had a utility all its own. If one approached the subject from the side of chemistry alone one arrived at a number of very interesting truths, but one would certainly not arrive so quickly or so effectively at the truths, which that institution was designed to elucidate, as if one approached the subject with biological consideration in mind. The biologist and the chemist had, no doubt, part of their field in common, but unless that part of the field which affected physiology was approached from the chemical side with a biological basis secrets of nature would unquestionably remain hidden and the progress of mankind in knowledge would be indefinitely retarded. The trustees of the gift had had the wisdom to perceive that if human suffering was to be alleviated on a wide scale, action must be based upon theories deeply founded upon study and experiment. They had heard a great deal about the horrors of cancer, and he believed that the attempt to organize all the forces of research in alleviating this plague was of infinite moment to their future. But if he might hazard a conjecture, if the time was ever to come when the intimate causes of this scourge were discovered, and a flood of light thrown upon the detailed facts which generations of medical men had accumulated, it would be through some discovery made by a student who was not specially thinking of cancer or of any other morbid growth, but whose discovery would open up some generalization, some new way of looking at familiar facts, which would entirely illuminate this profoundly obscure but all important question. If that happened, they might assuredly and confidently believe that it would happen in some school of biochemical research, where students had devoted themselves with a pure love of knowledge to the penetration of the secrets of nature, and, if it did occur, why should it not occur in the building in which they were now assembled. He was confident that this great school, under the leadership of Professor Gowland Hopkins, and those who were working with him, would accomplish that which Sir William Dunn desired, and that his successor who spoke in this room would not merely touch on the hopes of the future, but would be able to point to a long and accumulating series of discoveries made by students of research.

TOLL OF INFLUENZA

The lowest birthrate in England and Wales in any first quarter except during the war period was recorded during the first three months of this year. According to the Registrar General's return, the births numbered 185,486, and were 7,049 more than in the preceding quarter, but 7,484 fewer than in the corresponding period of 1923. The deaths registered numbered 160,279 and were 45,495 more than in the preceding quarter, and 35,559 more than in the corresponding quarter of 1923. Influenza was stated to be either a primary or contributory cause of death in 12,604 cases. Measured by the proportion of deaths of infants under one year of age to births registered, the infant mortality was equal to 102 per thousand, this being 8 per thousand below the average of the ten preceding first quarters.

EMPIRE HEALTH CONGRESS

Mr. Wheatley, Minister of Health, opened at Wembley on May 12th an Imperial Social Hygiene Congress. The assembly was organized by the National Council for Combating Venereal Disease and was attended by delegates from all the British Dominions and Crown Colonies. There were also representatives from the American Social Hygiene Association. Mr. Wheatley said that as Minister of Health he attached great importance to the conference and was particularly pleased with its imperial character. Sir Leslie Mackenzie, member of the Scottish Board of Health, said the war revealed the necessity for treating venereal diseases as disabling diseases, and not as incidents in the ethical behavior of men and women. This would only be doing what had been done generations ago for tuberculosis and smallpox. In the eight years since the Venereal Disease Regulations were issued in Scotland probably more cases had been treated than in the previous thirty or forty years. They might say that roughly the total cases in 1920 were 20,400, with 208,000 attendances; in 1923, 22,800, with 290,000

attendances. In 1920 the new cases were roughly, 13,300; and in 1923, 12,400. It would be difficult to name any official order either in England or Scotland, that had been more fully justified by the results. Dame Rachel Cowdry, director of the Social Hygiene Section of the League of Nations, read a paper on The International Position with Regard to Prostitution and the Suppression of the Traffic in Women and Children. She explained that the league was primarily and officially concerned only with traffic in women and children. It could not concern itself with prostitution which was a domestic problem, except in so far as prostitution concerned the international traffic in women and children. Professor Winnifred Cullis, of the London School of Medicine for Women, urged that biology, in preference to chemistry and physics, should be taught in the elementary schools. She pointed out that the subject would be of value in the education for the prevention of venereal diseases. It was easy to make it interesting and link it with sociology. If taught to elementary scholars it could readily be continued with adolescents. It ought to be in the curriculum of the training colleges.

Sir Arthur Newsholme read a paper on Some Aspects of Social Hygiene, in which he made strong plea for the right teaching of sex hygiene, beginning with instruction in self control from infancy onwards. Miss Alison Neilans, secretary of the association for moral and social hygiene, said that we could do little by law and police, but must change public opinion.

GENEVA LETTER

(*From our own correspondent*)

GENEVA, *April 1, 1924.*

ANAPHYLACTIC PHENOMENA

Although the anaphylactic phenomena are at present well known, the mechanism causing their development is less so, and several theories have been brought forward to explain them. The most recent theory regards anaphylactic shock as resulting from rupture of the vagosympathetic balance and this interpretation accords with a case recently observed by Dr. R. Lavielle. The patient, a female of twenty-three years, was suddenly seized on April 2, 1923, with a series of very impressive disturbances. She complained of violent colic and severe headache, while at the same time uncontrollable vomiting in closely repeated paroxysms occurred. The body was covered with a pruriginous exanthema, especially marked on the trunk and upper limbs, while the eyelids were the seat of such edema that the patient could not raise them. The history showed that on the day these morbid phenomena developed the menses had begun, and regardless of this fact the patient had taken a cold plunge in a pond. Under the influence of chilling, the menses ceased shortly after the development of the anaphylactic crisis. It is to be noted that the patient had previously had attacks of urticaria after ingestion of fish and strawberries. Given these data, an emmenagogue indication was exhibited, and in a few hours the menses recurred while at the same time most of the symptoms of shock retrogressed and only the edema of the lids and face were slow to subside although it had disappeared by the next day.

This typical anaphylactic crisis is merely interesting on account of its coexistence with the suppression of the ovarian functions. The absorption of blood consequent upon the arrest of the mensual flux, does not seem to be the cause of the crisis since, in the circumstances, the albumin entering the organism was not heterogeneous. On the one hand, if the close relationship existing between the sympathetic system and the endocrine glands—especially the ovary—be considered, as well as the short duration of the anaphylactic crisis and its brutal outburst, it seems logical to suppose that it was due to a reflex having multiple manifestations indicating a sudden disequilibrium of the vagosympathetic system.

SERUM ACCIDENTS

Dr. R. Clenet recently reported to the Société Médicale du Nord a curious case of serum accidents. The patient, a male, aged fifty-seven years, arteriosclerotic, with high blood pressure for many years, and presenting some azotemia, cut his finger slightly. The wound was dressed and an injection of antitetanic serum given. A few days later the patient was suddenly seized with a feeling of malaise in the night, and found that his head was badly swollen, especially the eyelids and lips. There was also some edema of the neck and the patient complained of a feeling of constriction at the throat with dyspnea and dysphagia. On the following day the swelling had somewhat subsided, but the edema had extended to the thorax and upper limbs. The body was covered with urticaria, the pain in the limbs was intense, there was anuria, and on the whole the general condition was bad. Two days later these symptoms retrogressed and recovery took place slowly.

Dr. Clenet pointed out that such severe symptoms were uncommon and recalled the fact that during the war while millions of antitetanic injections were given untoward accidents were uncommon and fleeting. This was probably due to the youth of the subjects and their general good physical condition. In older subjects, one must be prudent.

In the discussion which followed, Dr. Breton reported several similar cases and thought that their greater frequency at present was due to the greater freshness of the serum and because it was heated at 56° C. for a shorter time. Dr. Bloum mentioned an interesting case of a soldier in whom serious accidents occurred following the reinjection of antidiphtheritic serum and their immediate disappearance following a second injection of the same serum given at once. Finally, Dr. Descarpentries recalled that edema from serotherapy subsided rapidly when a few cubic centimetres of the patient's serum were injected.

VACCINATION LAWS VIOLATED

Not long ago, the Zurich police fined some six hundred persons for not having observed the law formulated by the Sanitary Commission of the city relating to vaccination. The court sustained the findings of the police and fined each person sixty francs (twelve dollars). The court also was affirmative in respect to the question, namely, if the Federal Council had the right to impose vaccination in case of epidemics of smallpox.

PERIARTERIAL SYMPATHECTOMY

A recent meeting of the Bordeaux Medical and Surgical Society was given up to the discussion of periarterial sympathectomy. Dr. Bardan and Dr. Mathey-Cornat reported twelve cases of old complicated ulcers in which this operation was done, as they had resisted all other therapeutic measures, even resection of the saphenous vein. The patients varied in age from fifty-three to sixty-nine years. The ulcers healed rapidly—in from six to forty-seven days, according to their size—after sympathectomy with a secondary vasodilatation verified by a series of local temperature charts, blood pressure, etc. Functional recuperation was satisfactory. These results led to the conclusion that periarterial sympathectomy is indicated in varicose ulcers combined with total saphenectomy. As to the ultimate outcome of these cases, a certain reserve must be made, although Dr. Charbonnel stated that he had had recoveries which had been permanent for two or three years. But he said that it must not be forgotten that these subjects often are arteriosclerotic so that the veins tear easily during operation. And more important still, the lymphatics were injected in these cases so that there was a possibility of the development of phlegmonous processes. Dr. Moulinier then pointed out that when arteritis existed in these cases, the results of sympathectomy would be *nil*.

In closing the discussion, Bardan and Mathey-Cornat showed that in some instances of failure following periarterial sympathectomy, this was due to errors in diagnosis and in support of this they referred to the case of a man, aged sixty-four years, who was submitted to femoral sympathectomy at the apex of Scarpa's triangle with transitory improvement lasting only a week. This failure was due to the fact that the case was in reality a thrombosis of the superficial and deep femorals.

TREATMENT OF MUMPS

The prophylactic treatment of mumps was the subject of an interesting paper read before the Paris Society of Therapeutics, by Dr. A. Challamel. The cases reported were closely followed and prove that incubation lasts for twenty days, that the phase of contagiousness must be extremely short, and that contagion of healthy subjects in most instances occurs during a few hours preceding the prodromal symptoms of the process. Hence, from the viewpoint of prophylaxis, as soon as a case of mumps develops, the subject who was in contact with the patient on the day before the latter manifested his symptoms, should be isolated rather than the patient himself. The isolation of suspected person on the nineteenth day following exposure would appear to be the only means of extinguishing a commencing epidemic.

MENINGOCOCCAL INFECTIONS

An important communication was made last fall to the French Congress of Medicine, by Dr. Dopfer, on the treatment of meningococcal infections. This eminent clinician stated that polyvalent serum should be injected before the results of the laboratory have been received. When the microbe has been determined a serum corresponding with the A, B, or C meningococcus should then be used, according to the organism identified in the laboratory. The serum should be given early and in massive doses, even in young children, and are to be repeated for several successive days.

This is the rule to follow: First give a polyvalent injection, then remove some cerebrospinal fluid for direct examination and culture. When the causative bacterium is identified, a corresponding serum is used. An apparent recovery should cause the injections to be stopped, upon condition that they are to be begun again should any of the symptoms recur. When recovery is delayed serotherapy is to be continued. Should a serum meningitis ensue, serotherapy must be stopped, and repeated lumbar puncture made. The serum should be injected both subcutaneously and in the spinal canal, the subcutaneous route being used to deal with the septicemia.

Vaccinotherapy is especially useful in cases where serotherapy does not seem to control the symptoms and autovaccines are to be preferred. Although its manner of action remains obscure, fixation abscess is an excellent adjuvant to treatment.

WASHINGTON LETTER

(*From our own correspondent*)

Washigton, *D. C., June 12, 1924.*

BRITTEN PERSONNEL BILL

At the conclusion of hearings before the House naval committee on the bill recommended by the Navy Department for equalization of promotion of staff officers with respect to those of the line, Representative Britten of that committee, introduced a bill of his own on that subject. His bill provides, so far as the Medical Corps of the Navy is concerned: one officer with the rank of rear admiral, thirty with the rank of captain, and sixty with the rank of commander. Mr. Britten states, in explanation of his bill, that he is convinced, as a result of the hearings before the naval committee on the equalization bill, that there are too many rear admirals and captains in the various staff corps, and that his bill gives each staff corps what he considers to be its required number of rear admirals, captains and commanders for the specific duties they are called upon to perform.

VERNAL HAY FEVER

The season for vernal hay fever, the less common but perhaps the more distressing type, has opened in Washington earlier than usual because of the cool weather, according to members of the medical staff in charge of the hay fever clinic maintained by the Woman's Welfare Association. Cool weather, it is stated, promotes rather than retards the flowering of the grasses, whose pollen grains, floating in the air in enormous quantities, cause periodic distress to hundreds of sufferers. Sweet vernal grass is in full bloom; others will follow in steady succession, extending the period of symptoms until the middle of July.

RITES FOR MRS. WORK

Funeral services for Mrs. Laura M. Work, wife of Dr. Hubert M. Work, former president of the American Medical Association, and at present the Secretary of the Interior, were held in the east room of the White House Monday, May 12, 1924, at 2

o'clock. Mrs. Work died Friday, May 9th, after an attack of heart disease. Original plans were for holding the obsequies in Secretary Work's apartment in Wardman Park Hotel, but use of the executive mansion, which in the past has rarely been the scene of final rites for any but Presidents and members of their immediate families, was tendered to the Secretary by President Coolidge. The Rev. Dr. Wallace Radcliffe, pastor emeritus of the New York Avenue Presbyterian Church, of which Mrs. Work was a member, conducted the services. Burial was in Arlington National Cemetery. On only three previous occasions has the east room of the White House been used for similar funerals.

WANTS POTOMAC WATER SAFE

Urgent need that the sanitary and drainage projects of the larger park areas be completed and that other work to be done to prevent the pollution of local streams and in the interest of sanitation was recommended in a report submitted by the sewage committee of the Board of Trade May 26, 1924. The civic body's executive committee voted to have the recommendations placed before Congress. Very little progress has been made since 1920, it was reported, towards the completion of the park sanitary work, which was originally recommended by the District sanitary enginee fifteen years ago. This relates to the sewerage and drainage systems of the great park areas such as the Upper Potomac, Rock Creek and Anacostia. The urban development in what is now known at Arlington County, was pointed out in the report. This area is in contact with the District for nearly six miles along the Potomac waterfront, and its population is said to be rapidly increasing, and as it is planned to install both water supply and sewerage, the Potomac will receive large bodies of sewage waters. There are many matters of sanitation in the city proper requiring attention, the committee said, including Piney Branch, in the Piney Branch Parkway between Rock Creek and Sixteenth Street. With the development of that section the sewerage system has become wholly inadequate, the report said. Although the appropriations allotted in recent years for sewerage have been larger in the aggregate, the sums allotted for the primary work of the great park areas have been materially less, the report stated.

CITATIONS FOR GALLANTRY

The following medical officer now in duty in Washington, as announced by the War Department, is cited for gallantry in action, and two stars will be placed upon the ribbon of the Philippine campaign medal awarded to him: Lieut. Col. Robert U. Patterson, Medical Corps, then first lieutenant. Action against insurgent forces at Fort Bacolod, Mindanao, April 8, 1903, and against hostile Moros at Fort Pitacus, Taraca River, Lake Lanao, Mindanao, May 4, 1903.

The following medical officers are cited for gallantry in action and a star will be placed upon the ribbon of the Philippine campaign: Brig. Gen. Walter D. McCaw, Medical Corps (one star), then major, United States Volunteers. Action against Spanish forces, Santiago, July 1, 1898. Col. Thomas J. Kirkpatrick, Medical Corps, retired (one star), then first lieutenant.

COMMISSIONS ACCEPTED IN THE RESERVE

Dr. Charles Ignatius Griffith, 1371 Monroe Street, Northwest, as a major in the Medical Corps, and Dr. Judge Ward Mankin, 3311 Thirteenth Street, Northwest, as a captain in the Medical Corps.

CHLORINE GAS FOR COLDS

Considerable interest attaches to the President's experiment with chlorine gas as a cure for the very severe cold from which he was suffering. A few hours before the President underwent the treatment, Secretary Weeks journeyed to the Munitions Building for the same purpose and it was at his suggestion that Mr. Coolidge underwent the treatment. Secretary Weeks took the gas some time ago, but under adverse conditions, as it was administered in his office. The Secretary and President are not the first in official life who have submitted to the treatment. Many Senators and Representatives have reported benefits from its use, and at the Capitol there is a chamber where several receive daily treatment. President Coolidge sat for fifty minutes in an airtight chamber and chatted (?) and read while atmosphere around him was being charged with the gas. With the President during the time was Lieut. Col. M. A. De Laney, Medical Corps, United States Army, who was in charge of the apparatus which releases the vapor.

POPULAR LECTURES ON PSYCHOLOGY

Under the auspices of the Washington Psychological Society and the Woman's Welfare Clinic, a psychological seminar on mind and health will be given by Dr. Tom A. Williams in the home of the Rev. Robert Johnston, rector of St. John's Episcopal Church, at 1754 Massachusetts Avenue. The lectures will be given every other day for a period of six days. Subjects of the lectures are as follows: First, perception, conception, affection and emotion in relation to the function of the nervous system; second, morbid delirium and the nature of hallucination and false interpretation; third, suggestion, inclination, prejudice and morbid trend; fourth, emotional perversions of fear, disgust, hate, jealousy, love and impulsion; fifth, motivation, nature of mind, fallacies about unconscious cerebration; sixth, discussion of various psychopathological theories.

FOOD POISONING OUTBREAK

Analysis of samples of the food which was suspected to have caused the sickness of students of the Dunbar and Armstrong schools has failed to indicate any cause for the illness, Dr. William C. Fowler, District Health Officer, announced May 27, 1924. A thorough bacteriological analysis both of the cooked and raw food was made by Dr. J. E. Noble and Dr. W. F. Landon, of the health office. An autopsy on a rat caught in the store where the suspected food was found, failed to throw light on the cause of the outbreak. All the students have recovered.

THIRTEEN NURSES GRADUATED

Thirteen young women who have finished their course at the Georgetown University Hospital Training School for Nurses received their diplomas at commencement exercises at 4:30 o'clock on the afternoon of May 25, 1924, in Gaston Hall, Georgetown College.

Book Reviews

DISEASES OF THE RESPIRATORY ORGANS

Precis de Pathologie Médicale. Tome II, Maladies de l'Appareil Respiratoire. FERNAND BEZANCON and S. I. DE JONG. Paris: Masson et Cie., 1923. Pp. 566.

Of the six volumes which are destined to replace Dieulafoy's well known textbooks on internal medicine, which were the guides of students and practitioners for two generations, the second volume, which treats of respiratory disease has just appeared. The authors, Professor Bezancon and Dr. de Jong, are well known authorities on the subject and distinguished for their studies, researches and publications on respiratory diseases. In this volume they have condensed their numerous essays on this subject and at the same time discussed classical facts and the works of other recent investigators.

After devoting a number of pages to the anatomy, physiology and pathology of the respiratory organs, the authors discuss the clinical aspect of diseases of the respiratory apparatus, such as bronchitis, bronchiectasis, asthma and emphysema, which have been the subject of their special attention and study during the last few years. Various forms of tuberculosis, such as the infant type, the glandular tuberculosis of childhood, the various aspects of the disease in adult life, pleurisy, pneumothorax, mediastinal involvement and trachiobronchial complications, are treated in a thorough manner. Numerous illustrations add to the clearness of the description of the pathological and clinical conditions in the various diseases. As a whole, the authors have presented a most valuable up to date textbook on respiratory diseases and are to be congratulated on the concise and practical way in which they have done their work.

TUBERCULOSIS FROM THE PATIENT'S VIEWPOINT

Tuberculosis. A Primer and Philosophy for Patient and Public. By MCDUGALD MCLEAN, B.A., B.Sc. (Oxford), M.D., (Johns Hopkins). Second Edition. New York: Journal of the Outdoor Life, 1924. Pp. 162.

It is always interesting to read a book on tuberculosis written by a tuberculous patient, and if the author of it is at the same time a physician it is doubly interesting. Unfortunately, the brilliant author, who made a valiant fight against tuberculosis, succumbed to the disease before the second edition saw the light of day. The first chapter deals with various methods of infection, and in their enumeration one little criticism might be justified inasmuch as the author does not call any attention to the infection by bacilliferous saliva. It is well known that children have frequently become infected by the kiss of a tuberculous individual or by a tuberculous mother testing the milk through the rubber nipple or the gruel with the same spoon used for the infant.

The description of the bacillus and the course of the disease are made lucid and interesting to the lay mind. The chapter on symptoms is very wisely headed as Danger Signals and is preceded by the words "Let thine ear now be attentive, and thine eyes open." The author makes a very just criticism of the habit of laymen, especially "ex-t.b.'s," of giving advice to tuberculous patients. In the chapter on Morale, he quotes William James on *Religion and Philosophy,* who said that we should "cultivate and practice a religion of healthy mindedness, courage, patience, optimism and reverence," to which might be added selfcontrol. In the chapter on climate, the author gives the present views which are to the effect that the climate is of less importance than the mode of life. A strong and always necessary plea is made for the abandonment of patent medicines and an equally strong protest is made against phthisiophobia.

The short biographical notes of "distinguished t. b.'s" are interesting and the author justly starts with Trudeau as the best known American. He then mentions Robert Louis Stevenson, Trudeau's most illustrious patient; the two great French clinicians and pathologists, Laennec and Grancher; the German poet, Schiller; the two German physicians who have done so much for the promulgation of the sanatorium idea, Brehmer and Dettweiler; and other less known but equally brave tuberculous patients who finally succumbed to the disease. It is regrettable that this young and brilliant author had so short a career as a teacher to laymen and physicians. May his little volume continue to be a comfort and inspiration to the tuberculous sufferer.

LARYNGEAL TUBERCULOSIS

Tuberculosis of the Larynx. Ten Years' Experience in a Sanatorium. By Sir St. Clair Thomson, M.D., F.C.R.P., F.R.C.S. London: Published by His Majesty's Stationery Office, 1924.

St. Clair Thomson's studies and statistics are based on observation of nearly three thousand cases in the King Edward VII Sanatorium, Midhurst. The numerical analysis and the teaching, as well, are applied to the various questions which arise in the etiology, symptomatology, diagnosis, treatment and prognosis of laryngeal tuberculosis. There is a detailed comparison of results seen in the three special methods of treatment by absolute silence, by whispers, and by galvanic cauterization, respectively. Short chapters are devoted to observations on tracheotomy, tuberculous otitis media, tuberculosis of the tongue, glands and scars of the neck, differentiation from syphilis, cancer, and aspergillosis of the larynx. The drawings, of which there are many, were prepared from sketches and descriptions made directly by the author. With the case histories, they are most interesting and instructive, but unfortunately rather coarsely and indistinctly reproduced.

SURGERY OF THE EAR

Chirurgie de l'Oreille, du Nez, du Pharynx et du Larynx. GEORGES LAURENS. Deuxieme édition, entièrement refondue, avec 792 figures dans le texte. Paris: Masson et Cie., 1924.

This, the second edition of Laurens's monumental treatise, is virtually a new work, inasmuch as many chapters have been rewritten, many added to, and the whole richly and, what is more, most instructively and clearly illustrated. Each operation in this wide field is described in detail with its indications, its technic and its sequelæ; at times, when required, by

a sketch of the topographical anatomy also. Among accessory procedures which are treated with care in detail, we note illumination, local anesthesia, and hemostasis of the operative field. Aftertreatment, too, is considered briefly. The importance of the visual factor in teaching has duly impressed the author who has accompanied and enriched his text with diagrams, schematic drawings, and a large number of reproductions of photographs. The completeness with which the field has been covered may be noted in the fact that the surgery of all the intracranial complications of otitis, the operations on the facial nerve, the esophagus, and on tumors of the cerebellopontine angle and of the acoustic nerve, are included. A monumental work, indeed.

MASTOID OPERATION

Handbuch der Speziellen Chirurgie des Ohres und der Oberen Luftwege. Herausgegeben von San.-Rat. Dr. L. Katz, Ludwigshafen a. Rh., und Prof. Dr. F. Blumenfeld, Wiesbaden. Radikale Freilegung der Mittelohrraeume (Radikaloperation oder Total aufmeisselung). II Band., Lieferung 9. Leipzig: Curt Kabitzsch, 1923.

This issue of the Katz-Blumenfeld Handbook deals, as indicated in the title, with the radical mastoid operation. The chapter was started by Preysing, and finished by Beyer. The field covered may be shown by a résumé of some items from the table of contents. There is a short historical survey of the development of the operation, and the indications for its performance in mastoiditis with and without subperiosteal abscess, in facial paralysis, tumors, progressive bone necrosis or cholesteatoma, suppuration involving the inner ear, sinus, or dura, and in borderline cases as a prophylactic, preventive measure. There are instructive chapters on the topographic anatomy of the attic and of the medial wall of the tympanic cavity. The technical details of the radical operation are given at length and with great care, the procedures of various authorities being described. There are many illustrations of uneven merit. Some of the colored plates, notably those representing various plastic operations, are beautiful and instructive. The whole work shows characteristic German thoroughness and care and a gratifying, because less characterstic, recognition of the work of otologists outside of Germany, notably those of France, England and America.

BIOLOGICAL RESEARCH

Handbuch der biologischen Arbeitsmethoden. Unter Mitarbeit von 500 bedeutenden Fachmännern, herausgegeben von Geh. Med.-Rat. Prof. Dr. Emil Abderhalden. Abt. XII, Methoden zur Erforschung der Leistungen von einzelligen Lebewesen, Heft. 2. Spezielle Methoden. Berlin und Wien: Urban & Schwarzenberg, 1924. Pp. 299-460.

In this number, Ernst G. Pringsheim discusses the technic of the stimulation experiments on unicellular organisms, including the subjects of phototaxis, thermotaxis, geotaxis, chemotaxis and aerotaxis. Paul Buchner takes up the subject of the intracellular symbiosis of animals with vegetable microorganisms. Stefania Lichtenstien treats of the methods of studying microorganisms in microscopical specimens and their methods of preparation and their methods of staining. This work is valuable to the laboratory technician.

DISORDERS OF DIGESTION

Treatment of Common Disorders of Digestion. By John L. Kantor, Ph.D., M.D. St. Louis: C. V. Mosby Company, 1924.

This book contains approximately two hundred and fifty pages devoted to the treatment of digestive disorders. In style, it is clear, concise and much to the point. It is presented in such a way as to carry the reader along step by step in the development of the therapeutics for various forms of indigestion, always giving the reason for the adoption of such measures as are recommended. X ray illustrations are given, especially for ptosis, delayed gastric emptying, atonic constipation, spastic constipation and dyschezia, which are very instructive. The treatment of ulcer is presented in an excellent manner. The book is well worth reading by any physician interested in the subject of gastroenterology.

FORENSIC PSYCHIATRY

Insanity and the Law. A Treatise on Forensic Psychiatry. By H. Douglas Singer, M.D., M.R.C.P. (London) and William O. Krohn, A.M., M.D., Ph.D. Philadelphia: P. Blakiston's Son and Company, 1924. Pp. 437.

This is a most timely book. Its aim is a presentation of the medical in relation to the legal phases of insanity. A quantity of pertinent material is presented which elucidates the intricate interrelationship which exists and the need for close cooperation between physician and lawmaker clearly emphasized. Many phases of insanity are discussed, mainly from a legal point of view, and the case material shown is well chosen. From this point of view the book fulfills its function admirably.

THE CONSCIOUS FACULTIES

Vom Wesen des Bewusstseins. Aus einer Lebenswissenschaftlichen Vorlesung. Von Dr. Ludwig Klages. Leipzig: Johann Ambrosius Barth, 1921. Pp. VI, 94.

This small volume will not appeal to a large class of readers but it will repay the thoughtful student. The latter will find his thought quickened to a new interest in the never ending consideration of the nature of consciousness, of the life which it represents, of the reality of those things by which life is surrounded or in which it represents itself, whether this reality is an actual one or has to do only with appearances and interpretations. Klages reviews and rejects the classical doctrines which have engaged psychological and philosophical thinkers in order to formulate his theory. He arrives at this through a careful examination of the activities and characteristics by which consciousness may be known. He treats each step with a careful, detailed penetration. He brings to bear upon his discussion the illustrative material of a cultural knowledge which furnishes him with a rich background on which to build his own theory. His own strong metaphysical tendency leads him, however, into a final solution which departs from the clearness of the facts by which he has in part at least supported his way. He looks toward a realm of investigation where the nature of life may be sought differently than in this vale of causal facts where it is necessary to tarry during an era of science. His solution already reflects the light that radiates upon him from this region but the simple facts of the humble causal territory are obscured by it. To him the connection of the soul with the body

is that of "the sense [das Sinnes] with the appearance of the sense." All that appears has a soul, which is known in the image of the thing. Everything lives, possessing this soul. He sees beyond consciousness, as its source, a fundamental spirit. The ego is the personally acting individual, the bearer of consciousness. Its body performs a practical function, that of receiving impressions from the external world and of reacting to these. The book is of interest as a manifestation of the direction of thought of this man of insight and of culture. Its style and its high aim in the search after the nature of life will hold the careful reader's attention.

VACCINE THERAPY

A Physician's Manual of Vaccine Therapy. By G. H. Sherman, M.D. Detroit: Press of the Bacteriological Laboratories of G. H. Sherman, 1924. Pp. 160.

This little book purports, so the preface states, to give in a concise comprehensive manner such facts and data as are pertinent to the application of bacterial vaccine therapy in the prophylaxis and treatment of infectious disease. "The facts and data given are the result of seventeen years of study and specialized effort, in addition to a great deal of research work and also clinical investigation carried on in hospitals, sanitoria, etc."

The volume opens with a chapter on vaccination in general, followed by a second outlining bacteriological information for the special use of the practitioner who wants this information in the briefest and most readily usable form. The portion of the book which gives it the title of a manual follows, with its data arranged alphabetically under the name of the disease, with cross references where necessary. Each entry, as, for instance, *asthma,* includes a brief outline of causation, nature of the disease, bacteria involved, and outline of treatment by vaccines. The appendix to the volume consists of quotations from the literature of the subject.

ANATOMY AND PHYSIOLOGY FOR CHILDREN

How Our Bodies Are Made. By R. M. Wilson, M.B., Ch.B. London: Henry Frowde and Hodder & Stoughton, 1923. Pp. 246.

To interest children in personal hygiene and furnish them with sufficient and proper physiological information to make them realize the significance of healthy habits of living, is a most important yet often difficult problem. The author of *How Our Bodies Are Made* has gone quite a distance toward solving this problem. He has put before us in his book descriptions of bodily functions in a very simple yet most attractive manner, and the story is told so entertainingly that any normally intelligent child could hardly fail to be interested in it. The use of analogies to help explain certain processes difficult to describe to children is very cleverly carried out, not only in the text but also in the numerous and excellent illustrations. For instance, the chapter called "The Hardest Worker in the World" is about the heart and its action; the "Soldiers at the Gate" are the teeth; "Red Submarines and White," the blood; "The Ruler" is the brain, etc. The chapter on the subject of sex, proper instruction in which has been the centre of so much controversy, is excellent. The explanation of cells and cellular structure which accompanies it is quite remarkable in that it is so simple that even a young child could easily understand it, yet it covers practically the whole ground as a description of cells, cell division, and final development in a complex organism.

FAMILY AND MONEY

Maestro Don Gesualdo. By Giovanni Verga. Translated by D. H. Lawrence. New York: Thomas Seltzer, 1924.

Anyone familiar with the Italian temperament, the intense rapidfire of thoughts, actions, emotions, will find in this novel of Verga's a faithful delineation of national characteristics. Add to this a human story and you have as readable a work of fiction as could be desired. The author has skilfully tuned the action of the piece into an instrument of style. Atmosphere is at the same time part of the tale's construction, just as it is in real life in Italy.

A man by dint of much striving succeeds. He pushes on and on in spite of his lowly origin. He allies himself to a leading family and the struggle between high and low wages back and forth. In no recent book of our acquaintance has the national family complex been so clearly shown, with the ruin attending its tyrannical sway. Maestro Don Gesualdo mounts upward until he is in sight of the twin gods, family and money. As soon as he tries to reach out for them, his descent begins. Once fired with this ambition, there is no cure. He falls and falls to the lowest depths, dependence, sordid death.

PSYCHOANALYSTS

Psychoanalysts Analyzed. By P. McBride, M.D. London: William Heinemann Medical Books, Ltd., 1924.

The author of this little lavender collection of clippings is serious enough to be the author of a comic serial. He believes the intestines are of greater import than the intellect. The arguments put forth are so puny that they are unworthy of the steel of even a tyro in psychoanalysis. A few of the author's dreams are cited, which strongly suggest impotence and senility.

Medicoliterary Notes.

Citizens of Brussels spending the summer at home may find the illusion of coolness at least by attending the new opera *Kaddara* being presented there at the Théâtre de la Monnaie. The scene of *Kaddara* is laid in Greenland and the characters are Eskimos. The composer is Haakon Borreson, a Norwegian. A French translation is being presented in Brussels.

* * * *

A recent study made by the U. S. Public Health Service of the extent of rural health service in this country and published in *Public Health Reports* for May 16th, shows that over eighty-seven per cent. of our rural population are as yet unprovided with health service approaching adequacy. Provision for this would mean a financial saving as well as the prevention of much mental and physical suffering and much unnecessary loss of human life.

The British Labor Government's political organ, the London *Daily Herald,* has recently published a table of the proportionate time absorbed by man's daily activities in a lifetime of seventy years. The statistician has estimated these as follows: sleep, twenty-three years; sickness, one and one-half years; eating, three years; washing, shaving and dressing, two and one-quarter years; school, one and

one-quarter years; work, eighteen years; reading, seven years; play, one and three-quarter years; entertainments, etc., one-half year; walking, trains, etc., two and one-quarter years; waiting for trains fifteen days; sweethearting, sixty days; idling, two and one-half years; sundries, seven years.

Juno and the Paycock is the diverting title of a new play now being presented at the Abbey Theatre in Dublin, and which, it is rumored, may be produced in the United States next season. The author is Mr. Sean O'Casey. His play is described as an extraordinary mixture of light comedy verging upon farce, with an undercurrent of bitter tragedy. However, there is an ending happy enough to please even Polyanna.

* * * *

The Health Book is the name of a sizeable volume by Royal S. Copeland, M.D., recently published by Harcourt, Brace & Co. The author states in his preface that the purpose of his book is "to tell in simple language how to relieve pain and what to do to prevent or to cure some of the many ailments which are liable to invade every home. I shall hope to explain how to meet the simple accidents, the sudden emergencies of factory, farm, and household, which are sometimes appalling if you don't know what to do," he tells us.

* * * *

Colonic Therapy in the Treatment of Disease is the subject discussed by O. Boto Schellberg in a volume recently issued by the American Institute of Medicine. Some of the chapter headings are: The evolution of the alimentary canal; intestinal bacteria; anatomy and physiology of the intestine; relation of colonic pathology to systemic infection; the futile enema; technic of colonic irrigation; antiseptics and bacterial implantations; fecal stasis and its consequences; the human machine.

* * * *

A recent issue of the *Living Age* quotes from the *North China Herald* the following amusing item: Missionaries who were motoring recently through Tondo, a district of Manila, in which there are many small Filipino and Chinese shops, were surprised to see the word "dammit" on several signboards. One of the women of the party expressed astonishment that the Filipinos had adopted English profanity to **such an extent as to use it** in their signs. It was then explained that "dammit" means clothing in the Tagalog dialect!

* * * *

The May issue of *Better Eyesight,* the small monthly devoted to the prevention and cure of imperfect sight without glasses, contains a number of interesting contributions. Among these are *Conical Cornea,* by Dr. W. H. Bates, editor; *Stories from the Clinic,* by Emily C. Lierman, and the *Mind's Eye,* by Edith McNamara.

* * * *

Dr. Trinidad de Tavera, director of the National Library and Museum, attracted considerable attention by expressing in the course of a recent lecture at Manila University the opinion that the Lord's Prayer is one of the curses of thte Philippines. He said the prayer taught the people to pray for their daily bread, and so encouraged them to trust to luck rather than to their brain and brawn. He also considered the coconut palm a curse because it tempted the owner. to bask in idleness. He advised the people to seek an example, not in Solomon's ant, but in their diligent Chinese neighbors.—*Living Age.*

Eyes and Their Future is the title of an article contributed by E. E. Fournier d'Albe to *The Nation and the Athenaeum of London.* The writer believes that, since light is an electrical phenomenon which will be transmitted along a wire when the question of suitable transformation is solved, in the future, distance, darkness, fog, and other intervening obstacles will lose most of their power of limiting vision. "The man of the twenty-first century will be able to sit at home and turn the leaves of the universe with the ease with which he now cons the pages of a favorite book."

* * * *

A Woman's national medical association has been organized in Germany, with Dr. Heusler as chairman, the purposes of which are set forth under four heads: 1, an opportunity for the women physicians of Germany to form a union; 2, the study of social hygiene from the standpoint of medical women; 3, the drafting of legislation in social hygiene from the point of view of the woman physician; 4, care of superannuated women colleagues and the creation of a fund to aid young women studying medicine. The league does not endeavor to study problems of medical science nor to protect its members' economic interests.—*Medical Woman's Journal.*

* * * *

The American Association for the Advancement of Science has issued a statement calling attention to the desirability of organizing a society for those interested in the history of science. The objects of this organization would be to encourage the study of the subject and to secure adequate financial support for the magazine *Isis,* edited by Dr. George Sarton. Dr. David Eugene Smith, professor of Mathematics at Teachers College, Columbia University, is in charge of the preliminary work of correspondence and organization.

* * * *

Spinsters everywhere will welcome an expression which is quickly coming into favor. It is no longer the custom in certain quarters to refer to single ladies of from forty to fifty as being on the shady side of forty or the sunny side of fifty. The correct thing to say is: "She is about tea-time age."—*London Morning Post.*

* * * *

The introduction into the mines of wet drills and the wide extension of underground ventilation, particularly through the use of blowers and flexible tubing, have led to so great a reduction of the death rate from miners' consumption in a metal mining community in the United States that premium rates for life insurance for miners in sound health have been reduced from twenty-five to forty per cent., according to a recent report of the Department of the Interior.

* * * *

The British Ministry of Health is making a special investigation as to why monks are so long lived. Dr. S. M. Copeman is visiting the monasteries scattered about Great Britain and will publish a report on his investigations. The London *Daily News* has become interested in the problem and recently sent a reporter to the Carthusian monastery at Cowfold. Here it was found that some of the monks over seventy were considered by their elder brethren as rather young and wildish; one of the porters said he was over eighty, and some of the gardeners were of the same age. The prior explained that it was due to their abstemious and regular lives and to the absence of cause for worry.

* * * *

Books for summer evenings, light yet interesting: *Recompense,* by Robert Keable (Putnam) continues the story of Peter and Julie begun in *Simon Called Peter* and carries the lives of both to a not altogether convincing climax: *The New Candide* by John Cournos (Boni & Liveright) is an amusingly written satire on modern life, extreme in spots; *Dream* by H. G. Wells (Macmillan) is one of that versatile writer's characteristically Utopian tales; *Christopher Columbus* by Johannes V. Jensen (Knopf) is one of the Long Journey series dealing with the period of discovery of America; *The Interpreter's House* by Struthers Burt (Scribner) is a story based on an unusual theme, the psychology of the middle- and so transient-aged, with their problem of chance and adaptation at a time when these do not "come easy" to new ideals and new ways of life; *Wine of Fury* by Leigh Rogers (Knopf), a young American who was in Russia at the time of the Revolution, is a story giving a vivid and understanding picture of those months; *Dog and Duck* by Arthur Machen (Knopf) is said to be also the name given to a famous drink which Mr. Machen serves every Saturday night to a group of ardent admirers. The recipe combines sauterne and gin; other entertaining works are *Safety Pin* by J. S. Fletcher (Putnam); *Book of Blanche,* by Dorothy Richardson (Little, Brown & Co.); *White Ship* by Anno Kallas, and *Children of the Age* by Knut Hamsun (Knopf); *African Clearings* by Jean Keynon MacKenzie (Houghton Mifflin); and *Darkened Windows* by Cornelia Kate Rathbone (Appleton).

Abstracts from Current Literature

RESPIRATORY DISORDERS

New Methods for the Study of the Pathology and Treatment of Tuberculous Disease.—Almroth E. Wright (*Lancet*, February 2, 1924) shows that cavernation appears to be due to a quite special chemical action exerted upon leucocytes by the tubercle bacillus. In all probability trypsin derived from the disintegrated leucocytes comes into operation on the fibrin. In exceptional cases where the blood has been very heavily implanted with tubercle, cavitation occurs without any apparent intervention of leucocytes. Here we have cavities filled with badly staining material in which tubercle bacilli are lying loose. Such cavitation is probably produced by a caseating necrosis. In the plasma clot the tubercle bacillus probably obtains some essential nutrient element from the fibrin of the clot which is not found in the serum. While it holds true generally that leucocytes exert an inhibitory influence upon the growth of the tubercle bacillus, there are important exceptions. Where leucocytes succumb to tuberculous attack the growth of the tubercle bacillus is distinctly favored. Polynuclear phagocytosis of tubercle bacilli is generally unsuccessful, and it then furnishes new foci of infection. The essential preliminary to treatment by implanting tubercle bacilli into the blood of phthisical patients will obviously be the prosecution of research into the phenomena of emigration. We require to study the laws that govern the emigration of the leucocytes from the blood or the blood clot, how to make leucocytes invade the tubercle foci as they admigrate to the bacilli in the blood of tuberculous patients, and to study generally the chemotactic properties and the migrational movements of the different species of leucocytes. The increased leucocytic reaction and the increased tuberculobactericidal power which distinguish the blood of tuberculous patients who have reacted to autoinoculations can be obtained by the addition of bacillary emulsion to the normal blood in vitro. However, the immunizing result will depend upon two factors operating in conjunction: 1, the dose of the living microbes implanted; 2, the quantum of vaccine which is superadded. With small additions of bacillary emulsion—doses ranging above and below one in fifty million of bacillary emulsion in blood—very large reduction of the tuberculous growth is obtained. With larger doses—doses up to one in five million of bacillary emulsion in blood—increased agglomeration of leucocytes round the tubercle bacilli is obtained. But with these larger doses the tubercle bacilli dispersed in the other regions of the preparation appear to grow more plentifully.

The Scientific Treatment of Tuberculosis.—Horace Lo Grasso (*Boston Medical and Surgical Journal*, February 7, 1924) emphasizes the following points:

1. Extrapulmonary tuberculosis is only a local manifestation of a constitutional disease, being usually secondary to lung or lymph node tuberculosis, and we must, therefore, treat the disease as a whole, and not its manifestations or complications.

2. Being a disease where resistance is lowered through lack of air and sunshine, excesses, mental and physical strain, and insufficient rest, it should be treated in the country air in environments conducive to good health, cheerfulness and contentment.

3. While fresh air and sunshine are most important curative factors in the treatment of tuberculosis, rickets, and other diseases due to the same predisposing conditions, they are of still greater value in preventing these diseases.

4. The sun is an analgesic and a dispeller of gloom.

5. The sun is a great muscle developer, as seen in the perfect musculature of those cases who have been in bed for years, and hence a very important factor in maintaining good positions and in preventing the development of deformity when the patient is up and about and convalescing. The long continued use of casts for immobilization leads to the abolition of function through atrophic degeneration of specialized structures.

6. The results of operations in extrapulmonary tuberculosis have not been sufficiently encouraging to countenance the general application of surgery, whereas the results of sun treatment, both in this country and in Europe, more than justify its use.

7. Sun cure is constructive, while operative procedures are destructive in that by attempting to destroy the focus of disease, the granulation tissue, which serves as a protective wall to the surrounding normal structures, is likewise broken down, opening new areas to infection and increasing the possibility of the disease spreading and developing into acute generalized tuberculosis.

8. Surgical measures destroy and never assist in the restoration of function in a joint, while in heliotherapy our aim is to restore or maintain this function.

9. Surgical intervention is justified only in those cases where, in spite of heliotherapy, and the resulting good general physical condition, the local lesion has not shown any satisfactory improvement. It is justified, to correct deformities developed during the course of treatment in spite of all the efforts to prevent them; to provide stability by an arthrodesis in a flail and useless articulation, and to evacuate abscesses, and this only by aspiration or a small incision when the pus is very thick. It is justified in renal tuberculosis of the advanced stage, when it is better to remove the kidney.

10. Artificial light in the treatment of extrapulmonary tuberculosis at its best is only a poor substitute and of questionable value.

Complement Fixation in Tuberculosis.—A Lisle Punch and A. Hope Gosse (*British Medical Journal*, September 22, 1923) endeavored to accomplish two purposes: 1. By a study of the literature to determine what, if any, definite advance in knowledge has been made since 1906, that is to say, what points of agreement have been arrived at by the various workers, and to determine if possible the causes of their points of disagreement. 2. To determine whether the method which the authors have employed of performing the test might reasonably be expected to give the reliable results they obtained. The variety of the antigens used partially explain the variability of the results obtained. Antigens may be divided into four main groups: 1, Suspension of whole or ground up tubercle bacilli; 2, antigens that may be classed as tuberculins; 3, extracts of derivatives of tubercle bacilli; and 4, extracts of normal or tuberculous tissues.

Generally, the most reliable results were obtained with antigens of the first group. A dilute suspension of tubercle bacilli in saline is undoubtedly the best antigen for this test. In cases of both syphilitic and tuberculous infection it appears possible to demonstrate the presence in the serum of both the lipotropic substances due to spirochetal infection and the specific antibodies to the tubercle bacillus. The same remarks apply with equal force to the antigens of the third group. The varying results obtained by different workers using different antigens is no doubt due in part to the difference of the antigen. The possible contributory causes are: 1, The lack of details in the description of the methods of preparation and of constancy of preparation; 2, a lack of detailed description of the technic used; 3, incomplete clinical control of the cases and their inaccurate classification; 4, the determination of the amount of fixation of complement necessary to be regarded as positive.

Complement Fixation Tests and Tuberculosis.—Arthur Sellers (*British Medical Journal*, September 22, 1923) compared two antigens, that of Wang and that of Besredka. The author still maintains his former position, namely, that he is not satisfied that complement fixation tests afford a reliable means of clinical diagnosis in tuberculous cases. The reaction is specific in the sense that under certain conditions the mixture serum plus extract will fix more complement than either of the two alone, but it seems that the property of fixing complement in the presence of an antigen derived from tubercle bacilli is shared by serums from cases other than those of tuberculosis. A positive result does not necessarily mean a definite tuberculous infection. Probably the number of such cases is not large, but the fact that they occur must not be ignored. The results with control specimens of the cerebrospinal fluid were disappointing. Apparently a positive reaction in a case of active tuberculosis is more favorable as regards prognosis than a negative, but where there are no signs of active tuberculosis a negative result points to a healed tuberculosis. A negative reaction followed by a positive indicates that improvement is setting in.

The Present Position of the Surgical Treatment of Pulmonary Tuberculosis.—J. Gravesen (*British Medical Journal,* September 22, 1923) believes that thoracoplasty is indicated in cases that are fit for lung collapse treatment, in which careful attempts to produce an artificial pneumothorax have failed. The individualization of the operation is the chief problem in plastic operations, and concerns two questions: 1. Should the thoracoplasty be partial or complete? 2. Should the operation be performed in one or more stages? The partial thoracoplasty may be sufficient either when the affection (as a cavity) is localized to a limited area, or when a partial pneumothorax has established collapse of the upper or, more frequently, the lower part of the lung. In cases of universal involvement of the lung, partial and ineffective pneumothorax should be discontinued in favor of complete thoracoplasty. If the patient is tall with strongly adherent muscles that cause difficult and violent manipulation at operation, the thoracoplasty should be done in two stages. On the other hand, a lean person in fair general health may well be operated on in one stage. A weakened, intoxicated person with rapid pulse should always be operated on in two stages. When there is doubt as to the condition of the socalled good lung a two stage operation is indicated, as a gradual collapse of the diseased lung is likely to be tolerated better than a sudden one.

Treatment of Tuberculous Diseases.—P. W. R. Boelke (*British Medical Journal,* December 29, 1923) asserts that the most uniformly successful results are obtainable with sodium morrhuate injections as compared with the various tuberculins, Marmorek's serum, various colloidal preparations, sugar injections, etc. Sodium morrhuate is valuable even in the very advanced stages of all forms of tuberculosis. It not only gives results equal to those achieved by tuberculin treatments, but it can arrest tuberculous diseases even where previous tuberculin or sanatorium treatments have failed. When given in correct doses without reactions it neither inconveniences the patient, as is the case with Koch's treatment, nor are the injections as painful as in Beraneck's treatment. It is therefore the best treatment in ambulatory cases. It is the only reliable remedy in hemorrhagic or feverish patients. It is a safe remedy if used correctly and free from those surprises sometimes following a tuberculin injection. Patients either free from active tuberculosis or in the last stages of the disease often show no local reaction and the sodium morrhuate may be given in increasing doses up to 1 c. c. or more without local reactions. Local reactions following sodium morrhuate injections are almost specific. Unless the drug is perfect the results of this treatment are negative. Many of the failures reported heretofore have been due to the poor condition of the sodium morrhuate.

Simulation of Active Pulmonary Tuberculosis by Painless Maxillary Sinusitis.—A. Lowndes Yates (*Lancet,* November 3, 1923) states that patients may have all the symptoms of pulmonary tuberculosis and yet be suffering from sinusitis without the presence of localized symptoms. These cases are frequently mistaken for pulmonary tuberculosis. These patients present not only the symptoms of tuberculosis, namely, cough, especially at night, morning sputum, which is yellow or green in color, and often nummular, progressive emaciation, a rise of temperature in the evening and after exercise, but also certain physical signs in the chest due apparently to bronchitis, which, while not typical of tuberculosis, nevertheless render the exclusion of the diagnosis of pulmonary tuberculosis difficult. The absence of tubercle bacilli in the sputum does not exclude the presence of pulmonary tuberculosis.

The Significance of the Sedimentation Reaction of Erythrocytes in the Diagnosis of Pulmonary Tuberculosis.—K. v. Neergard (*Schweizerische medizinische Wochenschrift,* December 6, 1923) affirms that the sedimentation reaction of the leucocytes renders excellent service in the diagnosis of activity or inactivity of pulmonary tuberculosis. In a large series of cases, formerly active, but later symptomless, there was moderate agreement between the reaction and the clinical findings. The clinically cured cases showed normal values. The reaction was found particularly valuable in the differentiation between neurasthenias and the symptoms of questionable tuberculosis (nightsweats, lassitude, etc.). In pronounced cases of tuberculosis, the rapidity of the sedimentation as a rule conformed with the severity of the disease and in the final stages it became somewhat diminished. With beginning pleurisy with effusion the values were high, but after the resorption of the exudate the values diminished. On monthly repetition of the test the increase, stability, and decrease in the values agreed fairly well with the course of the disease.

Permanent Results Following Artificial Pneumothorax.—H. Maendl (*Wiener klinische Wochenschrift,* October 25, 1923) postulates the following indications and contraindications for artificial pneumothorax: Unilateral pulmonary tuberculosis is the most important indication. This procedure should be applied only when all the other therapeutic measures have failed. In initial apical processes it is particularly contraindicated. The other indications include the following conditions: bronchiectasia, pulmonary abscess, pulmonary gangrene, severe pulmonary hemorrhage, the social indications (infectiousness and pregnancy), the symptomatic indication, pleurisy with effusion with a tuberculous process on the same side. It may be used for diagnostic purposes when a pulmonary tumor is suspected. The author has also applied pneumothorax in obstinate, constantly recurring, and very painful dry pleurisy.

Symptoms of Pulmonary Tuberculosis.—Olin S. Pettengill (*Boston Medical and Surgical Journal,* February 14, 1924) says that cough is the most common symptom complained of in incipient and moderately advanced stages. Productive cough occurs in a little more than half of the early cases. Tubercle bacilli are not present in sputum until ulceration of a focus of disease occurs communicating with the air passages and continues as long as the ulceration remains open. Physical signs, x ray, or a focal tuberculin reaction must prove the presence of pulmonary tuberculosis. Constitutional symptoms show the presence of clinical tuberculosis, and their severity show the degree of toxemia. The condition of the weight under ordinary conditions of life, susceptible to fatigue or ease of tire, the presence of afternoon fever and rapid pulse, are the foundations for making a prognosis. The time has passed when it is necessary to defend rest, both local and general, in the treatment of active tuberculosis, whether the rest be a retentive apparatus for joint, pneumothorax for lung, or whispered voice for the larynx. Rest in bed lessens the liberation of toxins from foci and conserves body energy.

Bone and Joint Tuberculosis.—R. Plato Schwartz (*Journal of Bone and Joint Surgery,* January, 1924) arrives at the following conclusions from his study. Tuberculosis of bones and joints, like all other local manifestations of this disease, should be regarded as the result of a generalized infectious process. Treatment of the local manifestations becomes most effective when it mobilizes the patient's resistance against the systemic infection which preceded the local lesion. Such a therapeutic agent is available in the form of heliotherapy. Immobilization is indicated for the correction of deformity and the relief of pain and muscle spasm. Definite departure from routine immobilization methods is indicated to prevent degeneration known to result from nonuse. Surgical measures may be indicated to improve function subsequent to healing of the tuberculous lesion. The restoration of function is a more desirable end result than ankylosis.

Nature and Pathogenesis of Bronchial Asthma and Its Relationship to Hay Fever and Other Affections.—On reviewing the disease picture, the etiology, the influence of the endocrine disturbances and of metabolism, the alimentary disturbances, etc., and the methods of treatment of bronchial asthma, Leo von Gordon (*Schweizerische medizinische Wochenschrift,* December 13, 1923) remarks that he never observed continued improvement of the asthma in severe cases after the appearance of fever, as, for example, in angina. There might be a relationship between asthma and the sympathetic nervous system, an increase in the sympathicotonia, which is frequently reduced in asthma, thereby producing an attack, as in that following adrenalin treatment.

Some Points in the Early Diagnosis of Pneumonia.—Tasker Howard (*New York State Journal of Medicine,* April 18, 1924) points out certain pitfalls in the early diagnosis of pneumonia. A patient lying on his side may present relative hyperresonance over the lung base on the lower side and he will tend to exhibit more intense breath sounds on this side. Râles over an affected lower lobe may appear when the patient lies on the affected side and disappear when he lies on the unaffected side. Bearing these points in mind one gains greatly in precision by examining the back of

every suspected pneumonia patient while he is lying first on one side and then on the other. Several positive findings in the early stage of pneumonia are to be emphasized: 1, the early increased respiratory rate; 2, the early leucocytosis; 3, that with or without consistent areas of hyperresonance, with diminished or roughened breathing, the presence of localized râles is most significant, and that these râles can best be brought out by having the patient cough.

SURGERY

Compression Leverage Fractures of the Ankle Joint.—J. H. Stevens (*Surgery, Gynecology and Obstetrics,* February, 1924), sums up his findings as follows:

Leverage fractures of the ankle under compression are, in reality, all of the same etiology, and vary simply from distribution of force and intensity of stress. This applies to most of the socalled simple fractures of the lower end of the fibula since the salient features of this fracture are present: i. e., ligamentous and tendon injury and a destroyed mortise permitting dislocation. Simple fractures of the fibula at any level, the result of direct violence without ligamentous rupture, do not belong to this type, but there are no compression leverage fractures of this kind involving the ankle joint. The inversion types are not usually attended with so great a destruction of ligaments, but there is an equal or more serious involvement of tendon sheaths, and a greater posterior dislocation is common in our experience.

The majority of these fractured ankles are not tremendously serious injuries and do not deserve the bad repute which is theirs at present. The bad results have been the result of immobilization and misdirection of effort on the part of the surgeon. Motion, active and passive, from the very beginning is the solution of the problem. Do not permit the ankle joint to stiffen in the first place. This is easy to prevent. It is only overcome, once it has occurred, at the expense of tremendous effort and months of time.

It is easy to reduce an ankle fracture, put it in a cast and look at it once a week, but it is fatal to the patient. If time is too important for one to devote twenty minutes a day to his ankle fracture, he had better turn them over to some other surgeon. No masseur is competent to do this work unless he is a surgeon and also competent to remedy any bad result. In the hands of a man who understands the pathology of the lesion, there is no danger.

From both the standpoint of economics and compensation insurance, this is a tremendously important subject. The time lost now, as a result of this injury, is enormous. It often extends over periods of months, or even a year or more, in individual cases, and this applies unfortunately to the mild type as well as the severe. Multiply this by the number of ankle fractures in a single year, and the time lost will be found to be enormous. A fracture of this type, without complications, should be returned to light employment in from four to seven weeks, with a practically normal foot, except for some swelling which in certain cases will persist for a long time.

Treatment of Fractures.—R. J. Cook (*Journal of Bone and Joint Surgery,* January, 1924) makes a comparative study of the various methods of treatment with the following results. When wounds are found to be infected by the streptococcus it is necessary to open the wound widely and desirable to treat the wound by the Carrel-Dakin method. When a gas bacillus infection is present, amputation above the level of the infection should be done. The failure to debride or the incomplete débridement of a wound has given opportunity in several cases for the development of gas bacillus infection. When débridement is well done such infection should not occur.

When it is possible to reduce the fracture at the time of the primary treatment it is found that the wound heals much more quickly. Contraindications were found in cases where the circulation was endangered, where there was danger of increasing the infection from the handling which such a procedure at times entails, or where it was difficult to keep the fracture reduced. When the fracture cannot be maintained in reduction by the replacement of the fractured ends in apposition it is better to wait and to do an open reduction after the primary wound has healed. The introduction of foreign material, such as tendon, wire, or plates, into the wound has led to difficulty and the development of a gas bacillus infection because of which amputation was subsequently necessary.

Osteomyelitis is more common in those cases treated by aseptic occlusion, drainage, and incomplete débridement. Bony deformity, as shortening of the limb, may occur in any type of treatment where it is not possible to maintain proper traction or to suture, wire plate or graft the fracture when indicated. Nonunion occurs most commonly because of infection, as does also delayed union. Nonunion and delayed union are also affected by lues.

The causes of the failure of treatment in cases treated by aseptic occlusion were incomplete drainage, infection, osteomyelitis, and sequestra. In simple drainage we find, likewise, the same causes of failure, with the additional one of the introduction of plates and wire. The main difficulty of cause of failure when the Carrel-Dakin treatment was used was the presence of sequestra or osteomyelitis. In the cases treated by débridement and suture the failures were due to incomplete débridement, as evidenced by the subsequent infection. When any form of treatment has failed it has been necessary to redrain the wound, to remove sequestra or osteomyelitic bone, and in the more serious cases of gas bacillus infection to amputate. The Carrel-Dakin treatment has been of much value in keeping the infection of wounds under control when the focus of infection has first been removed.

Wounds of compound fractures caused by direct violence heal, in general, more slowly than do those caused by indirect violence, because the traumatization of soft parts in the latter case is not as severe. However, this distinction is complicated by the fact that the extent of trauma and laceration of the wound has a marked relation to the time of healing required. It is possible, moreover, to require the necessary time of healing by débridement of the wound. In this series of cases we find that débridement reduces, by one half, the time required for the healing of lacerated wounds if we compare the lacerated wound treatment by aseptic occlusion and débridement. Puncture wounds treated by aseptic occlusion healed in about the same time as wounds treated by débridement.

The time which the patient must spend in the hospital is shortest under the method of débridement and suture, when successfully done. Next in order, in respect to time, is the method of primary occlusion, and next, the Carrel-Dakin technic.

Remote Results of Nerve Operations.—H. Platt and W. R. Bristow (*British Journal of Surgery,* January, 1924) present a thorough and detailed study with the following summary and conclusions.

1. The results of end to end suture in the case of gunshot lesions are for the most part imperfect both from a neurological and an economic viewpoint. In an average series of consecutive operations, complete failures will be found in about twenty per cent. The musculospiral nerve heads the list of recoveries, and may be expected to show practically complete restoration of function in at least fifty per cent. of the successful cases. The ulna and median nerves give disappointing results on the whole. In the former complete recovery in the intrinsic muscles of the hand is so rare as to be almost unknown; in the cases showing recovery neurotization of the hypothenar muscles alone is fairly constant. The economic results, however, in this nerve are often good, except in individuals whose occupation demands the finer coordinated movements of the fingers. In the median the sensory recovery is always inadequate, and this factor is the cause of the great depreciation in the function of the hand. In sutures of the median in the forearm, complete failure of recovery in the thenar muscles is frequently seen. The results of sciatic nerve sutures are poor, and a considerable number of such limbs come ultimately to amputation.

2. The outstanding causes of failure or imperfections—apart from delay, or gross errors in operative technic—are changes in the nerve above the line of suture—either interstitial fibrosis or an ascending neuritis—due in either case to wound infection, and topographical confusion in regeneration.

3. The operations of indirect nerve repair (with the possible exception of nervegrafting) have proved ineffective, and should be eliminated from the repertoire of peripheral nerve surgery. Investigations of the results of a small number of nervegrafting operations in this country suggest that these procedures are of limited value.

4. In the nerve lesions associated with profound irritation (causalgia), resection and suture, or the intraneural injection of seventy per cent. alcohol, will rarely fail to bring about immediate and complete relief of the pain, but at the cost of the signs and symptoms associated with complete division of that nerve.

In conclusion, the author wishes to make it clear that although a fair and critical survey of the nerve injuries of the war must leave one pessimistically inclined, yet there is a brighter side to the picture. War injuries are complicated by sepsis; but the prognosis for the nerve injuries of civil life must be vastly better, and the experience gained in nerve surgery on the scale which has been possible will help to crystallize our ideas for the benefit of the patient, and for an improvement in surgical teaching.

Prognosis in Epiphyseal Line Fractures.—M. K. Smith (*Annals of Surgery,* February, 1924) reports on thirty-three cases as follows: Thirty-three cases of epiphyseal line injuries have been followed up. Of these there were twenty-eight boys and five girls. The average age was twelve years plus. Only eight were ten years or less, the majority of these being in the lower humeral group. Fifteen per cent. showed premature or earlier ossification. This was found as promptly as six months after injury in one case and as late as two and one quarter years in another. Retardation of growth to a slight degree is common. It was present in thirty-three per cent. of twenty-one injuries to actively growing epiphyses of long bones. There was decided deformity from shortening in two cases of the twenty-one, or about ten per cent. Retardation of growth may persist without premature ossification. From a study of this series it appears that a retardation of growth is seldom compensated later. In lower radial injury with retardation a lesser ulna retardation is often associated, with or without ulna fracture. There seems to be a marked tendency for natural correction or compensation of epiphyseal separations to take place in such as have not been reduced.

INFECTIOUS DISEASES

Serum Prophylaxis of Measles.—S. E. Pesetke (*Journal of the Missouri State Medical Association,* March, 1924), believes that intramuscular injections of blood serum obtained during the second week of measles convalescence is highly effective in the prevention of measles. Immunity is temporary and of relatively short duration; perhaps fourteen months as a maximum. Late administration, that is from the fifth to sixth day of incubation, greatly modifies the clinical picture, producing a very mild course with establishment of complete immunity. This method is particularly adapted to the protection of large groups of children in institutions, especially those groups that are undernourished, rachitic or tuberculous.

Differential Diagnosis of the Exanthemata.—William L. Somerset (*New York State Journal of Medicine,* April 19, 1924), first considers scarlet fever which presents cardinal symptoms, namely, fever, sore throat or enanthem, skin eruption or exanthem. The fever and sore throat invariably appear at least twenty-four hours before the rash. The absence of any one of these three cardinal symptoms precludes the possibility of scarlet fever. Any throat or skin affection due to scarlet fever will invariably persist to the second or even third day after date of appearance. Smallpox is confused with syphilis and chickenpox. Syphilis works more slowly and chickenpox more quickly than smallpox. The umbilication of smallpox lesions is pathognomonic, again the four day prodromal period of small pox with remission of symptoms on appearance of the rash is characteristic.

An Immunity Reaction in Scarlet Fever.—W. Mair (*Lancet,* December 29, 1923), maintains that the Schultz-Charlton reaction is a toxin-antitoxin phenomenon. The rash and other changes in the skin are due to a scarlatinal toxin which has entered into combination with the tissue cells. Among the affected cells are those contractile elements which have been shown to exist even in capillary blood-vessels and to the function of which the normal tone of the capillaries is due. The toxin interferes with the function of these cells and a loss of tone of the capillaries results in erythema and the exudative phenomena as seen in the scarlet fever exanthem. The serum injected, when it gives a positive reaction, is supposed to contain an antitoxin which is able to dislodge and neutralize the toxin fixed in the cells, and so to restore their normal function in the area affected. The period of delay, twelve to twenty-four hours, in the appearance of the reaction, is no doubt due to the fact that the toxin is attached to the cells, and some time is thus required for its neutralization. When the rash fades in a normal manner the mechanism is probably different as this occurs long before any antitoxin can be demonstrated in the patient's blood.

Active Immunization of Adults Against Diphtheria.—Sanford B. Hooker (*Boston Medical and Surgical Journal,* February 21, 1924), says that systematic application of the Schick test and toxin-antitoxin immunization of susceptibles are procedures highly effective in the control of diphtheria among young adults who are later brought into close and prolonged contact with the disease. The results obtained in five hundred medical students and nurses are tabulated. About sixty per cent. of this class of individuals are susceptible to diphtheria. One series of toxin-antitoxin injections immunizes three fourths of them. A second series to those who remain Schick positive is at least equally effective. The systemic reactions which adults are prone to experience under the usual toxin-antitoxin dose schedule can be greatly reduced by using the local reaction as a guide to dosage increase. A considerable number of the subjects become hypersensitive to horse serum as a result of these injections and endermal serum tests; this is deemed undesirable and can be avoided by substituting goat antitoxin for the horse antitoxin now used in the mixtures. Clinical diphtheria among members of the tested group has been reduced over ninety-five per cent.

Studies on Varicella.—In a study of the Susceptibility of Rabbits to the Virus of Varicella, Thomas M. Rivers and William S. Tillett (*Journal of Experimental Medicine,* December, 1923), noted that irritation seemed to have a direct influence on the localization of the virus of varicella in the skin, which is indirect evidence that the virus is probably in the blood. A virus was recovered from the blood of varicella patients drawn during the first twenty-four hours after the appearance of the eruption. The blood in two c.c. amounts before clotting was injected into each testicle of normal rabbits. Four days later testicular emulsions were prepared. These were free from ordinary aerobic and anaerobic bacteria, but contained the virus and produced lesions in the cornea, skin and testicles of rabbits. It was possible to transmit the virus indefinitely from rabbit to rabbit by testicular inoculation.

Experimental Studies on the Etiology of Typhus Fever. In a study of the survival of the virus in collodion sacs implanted intraabdominally in guineapigs, Peter K. Olitsky and James E. McCartney (*Journal of Experimental Medicine,* December, 1923), employed collodion sacs described by Gates, and implanted them intraperitoneally in guineapigs after inoculation with the typhus virus. Animals so treated inoculated with blood containing typhus virus, showed no febrile or other reactions. When, on the other hand, the contents of the sacs removed after twenty-eight to thirty-one days were injected into normal guineapigs, these developed typical experimental typhus fever, showing that the virus was still active.

Hemolytic and Agglutinative Properties of Diphtheria Antitoxin.—Howard Osgood (*Buffalo General Hospital Bulletin,* January, 1924), states that the samples of diphtheria antitoxin examined had the power of lacking human erythrocytes when these were added to the undiluted antitoxin and to low dilutions of it in physiological salt solution. This laking was due, at least in the main part, to the tricresol present as a preservative. This tricresol laking is inhibited by the presence of human blood serum in the proportion of one part of serum to six or seven parts of antitoxin or dilution of the same. A larger proportion of blood serum would probably completely inhibit the tricresol laking in every lot. The great excess of blood serum present when antitoxin is injected intravenously would prevent any such laking in the patient, both by dilution and by its specific inhibiting power. All lots of antitoxin showed strong, though somewhat atypical, agglutination of human erythrocytes, when tested undiluted and in 1.2 dilution. It seems possible that this weak agglutinative activity would have no effect on the patient's erythrocytes, when the antitoxin is injected intravenously.

SYSTOLIC BLOOD PRESSURE DECEPTION TEST RESULT NOT ADMISSIBLE IN EVIDENCE

In a murder case, counsel for the defendant in the course of the trial offered an expert witness to testify to the result of a systolic blood pressure deception test which had been made upon the defendant prior to the trial, but objection to the offer was sustained. The court also denied an offer to have the proffered witness conduct a test in the presence of the jury. On appeal, counsel based their case, which presents a novel question on which no precedents directly in point had been found, on the rule which admits in evidence the opinions of witnesses skilled in a particular science, art, or trade to which the question involved relates, when such question does not lie within the range of common experience or common knowledge.

The Court of Appeals of the District of Columbia, Frye v. United States, 293 Fed. 1013, affirming the judgment of conviction, says: "Just when a scientific principle or discovery crosses the line between the experimental and demonstrable stages is difficult to define. Somewhere in this twilight zone the evidential force of the principle must be recognized, and while courts will go a long way in admitting expert testimony deduced from a well recognized scientific principle or discovery, the thing from which the deduction is made must be sufficiently established to have gained general acceptance in the particular field in which it belongs.

"We think the systolic blood pressure deception test has not yet gained such standing and scientific recognition among physiological and psychological authorities as would justify the courts in admitting expert testimony deduced from the discovery, development, and experiments thus far made."

MALPRACTICE IN USING ELECTRICAL TREATMENT NOT SHOWN BY THE EVIDENCE

In an action for malpractice the question was whether the defendant physician by unskilful electrical treatment of a lump between the plaintiff's breasts burned her on the chest about midway between the breasts and, as a consequence, injured her. The plaintiff testified that a condition for which the defendant had treated her about four years before, the nature and cause of which were not shown by the evidence, had continued and resulted in the swelling, that the defendant had advised an operation and, on her refusal to undergo it, had treated her with blue ray electricity and later with a different appliance which had burned her; that he had then advised her to see a certain expert, whom she saw but from whom she received no treatment; and that she then went to another physician for treatment for a condition claimed to be a result of the burns. The defendant testified that when the plaintiff consulted him about the swelling, which was probably traumatic, due to a fall, he advised a surgical operation, but she said she was afraid of an operation; that he then told her the only treatment he could advise was a high frequency treatment, which is the same as the blue flame; that he gave her twelve such treatments, each lasting five or six minutes, at intervals of about twice a week. He said he never had a therapeutic or heat producing lamp; that he ultimately told the plaintiff the treatments were doing her no good, and gave her a letter to an expert, telling her to come back and let him know what the expert thought of it, and that he did not see her again; and that the swelling remained practically the same as when he first saw her. Medical experts testified that a therapeutic lamp such as the plaintiff said the defendant had used would not have caused burns of the nature complained of, and that the defendant's treatment was proper under the circumstances shown. It was not shown that the burns resulted from the treatment.

The Illinois Appellate Court, Graiziger v. Heussler, 229 Ill. App. 365, held that a judgment against the defendant was against the evidence, and it was reversed, with a finding of fact that the evidence did not show a lack of ordinary care on the part of the defendant.

The court said, in part: "As to the element of injury, arising as a result of the alleged unskilfulness, it is the obligation of the plaintiff to prove not only a lack of ordinary care on the part of the defendant, but in addition thereto, that some injury occurred as a consequence. In other words, the defendant is not liable merely because he failed to exercise ordinary care, but is only liable when it is also proven that some injury has resulted therefrom. Further, the principle of *res ipsa loquitur* does not apply. The mere fact that the abnormal condition, which existed at the time of the treatment complained of, for a time grew worse, is not of itself any evidence that the treatment was unskilful. A medical practitioner is not an insurer."

INSUFFICIENT EVIDENCE OF CORPUS DELICTI

In a murder case, the evidence disclosed that a young man, 21 years old, of slight stature, weighing 135 pounds, whose arms had been injured and incapacitated by a previous railway accident, struck deceased two blows with his bare fist in the face, leaving slight discoloration of the skin; that deceased was a large man weighing 247 pounds and 5 feet 9 inches in height and of robust physical prowess; that the deceased had been within a few hours previous drinking moonshine and other liquors to intoxication, and upon being struck sank down on the street slowly as if lying down, and in a few minutes afterwards expired, the autopsy disclosing a blood clot at the base of the brain as the cause of death, but no congestion of the brain, nor any internal evidences of injury to the brain other than the blood clot; that there was a slight discoloration on the inside of the skin on the back of the head, discernible only after the scalp had been removed, and no injury to the skull, and the medical expert, not experienced in brain surgery, said death might possibly have resulted from the blows; and it appeared that there was no ill feeling between the parties, and no motive for the act, the Supreme Court of Appeals of West Virginia holds, State v. Roush, 120 S. E. 304, that the corpus delicti had not been proved to the full measure of the law, and a verdict of murder was set aside and a new trial awarded.

PROXIMATE CAUSE OF SPREAD OF DISEASE

The Oklahoma Supreme Court, City of Shawnee v. Jeter, 221 Pac. 758, states as an almost universal holding of the courts, that the care of persons afflicted with contagious diseases is a governmental function, and consequently a municipal corporation is not liable in damages for the neglect of its officers in performing services in aid of that function. The health officer of a city, in placing a stranger afflicted with smallpox in the isolation ward of the city hospital, is carrying out one of its governmental duties.

In an action against a city for the death of a patient in the city hospital, alleged to have been caused by the negligent acts of the matron or her assistants in permitting nurses to go in and out of the isolation ward and through the hospital, resulting in the patient contracting smallpox, it was held that there was no evidence to show that this had been done except at a time when the patient had already contracted smallpox, so that this, if negligence, could not have been the proximate cause of the injury.

Following the Acute Infections

prompt and uncomplicated recovery almost always calls for the systematic use of an efficient restorative tonic—a preparation that will place the least possible burden on the digestive and assimilative functions of the body, but will at the same time supply the support so urgently needed by weakened and exhausted tissues.

The constantly increasing number of medical men that have come to rely on

Gray's Glycerine Tonic Comp.

as a reconstructive tonic, tell beyond all question of its efficiency for the foregoing purposes. Under its use, functional activity is promptly increased, the nutrition is rapidly improved, and the defensive forces of the body are substantially raised.

Gray's Glycerine Tonic Comp. is thus recognized by the busy practitioner as a body-builder to which he can "pin his faith" as a dependable means of promoting convalescence and hastening recovery.

A trial of this reliable tonic will show its exceptional value following the acute infections prevalent at this season of the year.

VALENTINE'S PREPARATION
NUTRIO PERMIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS—Dissolve one tea-spoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

The Earlier Methods Employed in the Treatment of Syphilis.—Dr. Francis R. Packard (*Annals of Medical History*, September, 1923) writes that it is now generally believed that syphilis existed in Europe long before 1495, the year in which it sprang suddenly into such terrible prominence. It was called by many different names, especially leprosy. Before 1500, there were some 19,000 socalled leper hospitals scattered over Europe, which completely vanished as syphilis became better understood. The name syphilis was first used in connection with the disease by Fracastorius (1530) in a poem called *Syphilis sive morbus*, in which the word is used as the name of a shepherd who is stricken because of a sacrilegious act. Before that time, the disease was called *morbus venereus*, or more popularly, the French disease, the Spanish disease, or the Neapolitan disease. "Europeans, tired of attributing it to one another, called it the new disease and blamed its introduction on the sailors of Columbus." Until the latter part of the eighteenth century, all venereal sores or manifestations, including gonorrhea, were called syphilitic.

Quackery has predominated in the treatment of venereal diseases, unfortunately, from the earliest times to the present. A curious fact is that the most successful quack remedies of the sixteenth century contained mercury, a favorite medicine for leprosy, administered either by fumigation or inunction.

A poem on syphilis more than thirty years earlier than that of Fracastorius, though less widely known, was one by Francisco Lopez de Villabos, physician to King Ferdinand of Spain, entitled On the Contagious and Accursed Buboes. In this the treatment of salivation with mercury administered by fumigations or inunctions is vigorously condemned, and its use as an ointment only advocated. Fracastorius, who ascribed the disease to astrological agencies, prescribed a treatment through salivation the principles of which were the chief mainstays of the therapeutics of syphilis for hundreds of years. He advocates at first trial of a series of simpler remedies having to do with climate, exercise, diet, bleeding, and the drinking of certain decoctions and application of topical remedies. If these fail, fumigations composed of styrax, cinnabar, antimony and incense should be resorted to. These fumigations should be confined to those parts of the body which are the seats of eruptions or ulcers. Mercury is preferred as a basis for these fumigations, and was administered in an ointment mixed with black hellebore, orris root, galbanum, asafetida, oil of mastic and oil of native sulphur.

Benvenuto Cellini in his writings lauds Berengarius of Capri for his successful treatment of syphilis with mercurial inunctions. He adds, however, that Berengarius departed from Rome very hastily and wisely because all his patients relapsed, and he would have been murdered, had he stayed. This fifteenth century treatment by mercurial inunctions was carried out so as to ensure salivation. The patient was smeared from head to foot with the mixture containing the mercury applied with a brush, usually by a barber, surgeon or apothecary. Then he was put into a great tub or cask and sweated. Of course many died from mercurial poisoning or exhaustion. Paré's treatment, based on de Héry's, recommends four methods of cure: guaiac decoctions, rubbing with ointments containing mercury or sulphur, mercury plasters, and fumigation with cinnabar; all these are based on sweating. Paracelsus (1493) is usually given the credit for popularizing the internal use of mercury in syphilis. Mattioli (1501) is also credited for giving mercury internally. The first known formula for mercury in pill form was one which Barbarossa, pirate king of Algiers, sent to Francis I. This formula, slightly modified, was that of the famous Belloste pills, still retained in the French codex.

Next as a remedy came the "sacred wood," guaiac, of which Fracastorius also speaks; then, Chinese smilax, extolled by Vesalius, later supplanted by sarsaparilla, followed by the gold treatment, and finally potassium iodide, ascribed to William Wallace of Dublin (1833).

The Seasonal Factor in Mortality.—Interest is being centred more and more upon the seasonal fluctuation of sickness and death and upon the possible influence of weather factors on health conditions. The first quarter of the year in the north temperate zone carries with it the heaviest deathrate. From that point onward, the rates of sickness and of death decline to a minimum in the fall months. The figures then gradually rise with the close of the year.

These facts of seasonal variation have been generally appreciated. But, there are many implications which are worthy of detailed treatment. In a recent issue of the *Statistical Bulletin* of the Metropolitan Life Insurance Company, it was shown that the deathrate varied inversely with the temperature. It was calculated that if the deathrate were always as low as when the temperature averaged 65° F., ten per cent. of the deaths in the city might have been avoided. Conclusions of this kind are very important. They show the extent to which departures in temperature and other weather elements affect the deathrate and at what times in the year conscious, deliberate attempts should be made by the individual to safeguard himself and the members of his family. Advances in ventilation engineering and in building construction have made it possible to safeguard mankind from the vagaries of weather and from unwholesome indoor conditions.

Investigations into the effect of weather upon mortality in various seasons of the year make necessary that the element of normal seasonal variation be understood and properly provided for in the calculation. Thus, if a January rate of 10.1 is followed by a February rate of 12.3 per 1,000, the question is how much of this increase is due to normal seasonal variation and how much to some other but unusual mortality factor. It is possible that there may have been an exceptional increase in the February death rate due to an outbreak of an epidemic disease or to unusually severe weather conditions. The influence of any such exceptional factors can be measured approximately by determining the extent to which the increase in February over January exceeds the expected month to month rise usual in these two months.

An Effective Remedy *for* Nervous Sleepless Patients

Neuronidia

Palatable Well-Tolerated Reliable

Allaying Restlessness and Producing Refreshing Sleep

Especially indicated in insomnia from mental strain, neurasthenia and other neuroses; also an excellent sedative in sea-sickness.

IACKENSACK, - - - - - NEW JERSEY, U. S. A.

The Doctor and Public Health.—There are certain small nations which have low death rates, although there seems to be little done in the way of public health work as such. The low mortality is credited in part to favorable conditions of climate, food, and outdoor life, but it is said to be largely due to the influence of a well trained and efficient medical profession which has the confidence of a public intelligent enough to choose and trust expert guidance. Hence sanitation, quarantine, inoculation, and hygienic living become a part of daily routine and are fixed in the official machinery, social customs, and personal habits of the people.

In all lands doctors are an essential part of the public health movement. They report births, causes of death, and cases of communicable disease. Upon them depends the introduction of new resources of diagnosis and treatment; for good or ill they educate their patients; they influence public opinion for or against preventive policies. No health service can prosper permanently unless it can command the loyal support of competent local practising physicians. The presence of physicians, poorly trained or with no interest in preventive medicine, or of representatives of various occult, empirical, or fraudulent cults is a serious handicap to effective sanitation and hygiene.

It follows that medical education plays an essential part in the leadership and success of public health work. The Rockefeller Foundation is concerned, therefore, in aiding influential medical schools in many parts of the world to improve their facilities, to strengthen their teaching staffs, to perfect their methods, to maintain high standards, and gradually, in the words of a distinguished British medical authority, to "permeate the curriculum with the preventive idea." With respect to the last suggestion the International Health Board is supporting in a leading American medical school a plan which aims at getting every teacher to emphasize the preventive and community aspects of every topic with which he deals in his regular courses.

Goitre Abundant Where Iodine Is Scarce.—Further confirmation of the relation between a lack of iodine and the presence of goitre is presented in a report to the American Medical Association by Dr. J. F. McClendon and J. C. Hathaway of the University of Minnesota. They analyzed samples of drinking water and of food from all parts of the country, and found that where iodine was rare, goitre was abundant.

Water from Lake Superior near Duluth, Minn., and drinking water from Spokane, Wash., and from Rockford, Ill., contain only about one part of iodine to one million parts of water. All these places are in regions where goitre is relatively common. On the other hand, water from Mexia, Texas, and from Stanford, Cal., where goitre is rare, was found to contain respectively 18,000 and 10,000 parts of iodine to the million parts of water. If regions in which the proportion of iodine in the water is less than twenty-two parts to the million be charted, the map closely coincides with one in which high percentages of goitre in human beings is found. Sault Ste. Marie, Mich., and Rochester, N. Y., are adding small amounts of iodine to water in the city reservoirs as a preventive of goitre.

The Social Significance of Medicine*

LEWELLYS F. BARKER, M.D., LL.D.,
Baltimore, Md.

In times of peace the individual is prone to an exaggerated assertion of self at the expense of society; in times of war, or when war is threatened, bonds that hold individuals together in a nation become firmer and collective interests temporarily become paramount. At all times it is desirable that a proper balance be maintained between the activities that favor individual or group welfare and those that favor the welfare of society as a whole; for, on the one hand, the individual must do well if society is to prosper, and, on the other hand, society must be preserved and strengthened through the loyalty, devotion and obedience of its units, even at the sacrifice of some of their individual interests, if the individual is to have freedom of opportunity for the exercise of his faculties. It would seem desirable, therefore, that each person, and each occupational or professional group, should, occasionally, give some special thought to the matter of his and its social meaning and value. This is my excuse for asking your attention to a brief consideration of the social significance of medicine.

In estimating the value of a person or of a professional group to society, one must try to determine the relation of the activities of that person, or of that group, to the attainment of the aims of society as a whole. In our modern civilization the aim of society would seem to be the attainment and maintenance of those conditions in its members and in their environment that will, to the greatest number of units, permit of the greatest freedom in exercising harmoniously their various faculties, each for his own and at the same time for the collective welfare. Theoretically, in a perfect state, the men and women who constitute it could and would lead lives through which the highest individual good and the highest collective good would simultaneously be realized. But the perfect state never has existed, and never will exist, except as a fiction, an ideal toward which we may work, a standard by which our imperfect collective achievements may be measured and valued.

If these preliminary assumptions be agreed to, my task resolves itself into a consideration of the importance of the functions of the members of the medical profession for promoting the freedom of social units to live full and well proportioned lives, lives that are individually good because of the proper exercise of all the liver's faculties and that promote the collective good because in them the social virtues are practised. And since the kind of life a person lives depends upon his inborn capacities and upon the surroundings they are immersed in after birth, the business before us is to inquire in how far medicine does and can influence the constitutional and environmental conditions of man, which determine his functions and the modes of their exercise. In undertaking as its province the maintenance of health and the prevention and cure of disease in human beings, the medical profession has entered upon a gigantic enterprise, one that makes great demands upon the heads and hearts of those who engage in it, one that is full of promise for the welfare of individual persons, and one that when comprehensively viewed will be seen, I must believe, to be so significant for the whole of society as to demand, indeed to guarantee, society's warm support and high esteem.

If the view of the functions of medicine that I shall try to outline be well founded, then our profession can lay claim to at least equal rank with her sister profession of the law in importance for the promotion of collective welfare. The great philosopher David Hume, speaking of the law, said: "Man born in a family is compelled to maintain society from necessity, from natural inclination and from habit. The same creature, in his further progress, is engaged to establish political society in order to administer justice, without which there can be no peace among them, nor safety, nor mutual intercourse. We are therefore to look upon all the vast apparatus of our government as having ultimately no other object or purpose but the distribution of justice, or, in other words, the support of the judges. Kings and parliaments, fleets and armies, officers of the court and revenue, ambassadors, ministers and privy councillors are all subordinate in the end to this part of administration." Truly a noble view of the law! My aim is to show that medicine, which has as its object the healthy mind in the healthy body, and which devises and executes eugenic and euthenic programs directed toward this end, performs a service to society that is equally indispensable, a service, indeed, upon which, on due consideration, the very practice of justice itself will be seen to depend.

*An address to the Fellows of the College of Physicians, Philadelphia, October 3, 1923.

Medical men in ancient times doubtless began their activities by striving to be of help to those who were sick, injured or otherwise in distress, applying all the simple remedies that the method of trial and error taught them to be of value for their care or alleviation. From these primitive beginnings the great work of the medical profession has gradually evolved. The curiosity excited by deformity and disease stimulated the simpler observational investigations that were the forerunners of the abstruse researches of the modern medical experimenter and discoverer; the primitive remedial activities became gradually extended to culminate in the rich therapeutical armamentarium and the elaborate practical technical methods of the presentday medical and surgical practitioner. The recognition of the disastrous consequences of disease, stimulating observation and inquiry into conditions of health, gave rise to the earlier rules for the preservation of health and the prevention of disease that have been transformed during centuries of change into the more precise and further reaching regulations of contemporary personal, communal and racial hygiene. And the methods of passing on medical lore from person to person, from experienced master to apprenticed pupil, gradually underwent development and differentiation into our modern agencies and institutions for the diffusion of knowledge of medical science and for training in the art of applying it—our great schools of medicine and of hygiene with their specialized faculty members, our libraries with their rich stores in medical textbooks, monographs and journals, and our local, regional, national and international medical associations for the quick transmission and wholesome, penetrative criticism of new medical facts and impulses. Out of the chaos of ancient medical myths the whimsical and extravagant notions of antique therapy, the hygienic traditions of primitive peoples and the defective early methods of transmitting medical knowledge have emerged the medical research, the medical practice, the preventive medicine, the public health measures and the scientific medical education that are characteristic of the civilization of the twentieth century. Those members of society to whom have been entrusted the special function of preserving health and of curing and preventing disease have undoubtedly through the ages felt in ever increasing measure the magnitude and the seriousness of their responsibilities. They have achieved results and left records that give abundant reason for professional pride; they have opened paths for work that are full of promise to those who will further walk in them, and they have by their intellects and imaginations conceived of worthy ideals that spur us, their successors, to devote our best efforts to the attempt to realize them.

Since society achieves its own welfare through the life activities of its constituent units, let us examine the ways in which the medical profession of today becomes socially significant through promotion of the selfrealization of individuals in social service. What does the medical profession do, on the one hand, to help equalize individuals in their freedom to exercise all their functions, to find adequate expression for the whole of their personality, and, on the other hand, to aid social justice by favoring a balanced proportion among the interests of those who have equal rights to the possession of interests. In other words, in how far are physicians of use in helping people to direct their own lives by reason and conscience so that they will, while exercising their own powers to the full, perform their social functions better; and, in how far are they influential in helping persons not only to defend the right to be themselves but also to recognize the obligation to refrain from interference with the rights of others? The greater the service medicine can render to society in these two main directions—that of facilitating the free and harmonious exercise of their functions by the social units and that of harmonizing the activities of these units so that in society there may be fairness for all—the larger will be its social import.

Medical investigators in their studies of physical diseases and of abnormal thought, feeling and behavior have discovered and described enormous numbers of physical and mental maladies and irregularities. They have, too, more or less successfully inquired into their causes, and they are ever striving to follow in series the links in the chains that connect these causes with those ultimate consequences that we know as signs of structural change and as symptoms of pathological functioning. The causes that they find are sometimes defects in the original make-up of hereditary qualities, sometimes malign influences—physical, chemical, biological or social—in the environment and more often still a combination of faulty hereditary tendency with environmental injury. And among the consequences of abnormal function it is always interesting to observe in how far the damage to the individual and the corresponding hindrance to his welfare impair also his social usefulness, or, as they do in many instances, make him actually a social menace. We know that physical disease involves both personal and public loss. Malaria and yellow fever not only prostrated their victims, but they prevented for a long time the development of Cuba and the building of the Panama Canal. The tubercle bacillus, the Treponema pallidum and the hookworm render miserable those who are personally attacked by them; they also are an economic drain and they exert a dispiriting influence upon the families of the infected. Similarly, mental diseases and abnormalities are subversive of both personal and collective good; the insane, the imbecile, the criminal and even the psychoneurotic lead imperfect lives themselves; but, besides, they lessen the happiness and increase the expenses of the families they belong to and they often seriously endanger general welfare in the communities in which they live. It is to the credit of modern neurology and psychiatry that they have done much to further social progress by changing our attitude toward social offenders. In the perpetrators of social evil they have sought the true causes—physiological, psychological, economic, social—of their moral obliquity, and are pointing the way to remedies that those flooded with the passion of punitive hate could scarcely find. Medicine, long ago discovering the rôle of natural law in disease, rescued the physically sick from those who would exorcise demons; later, she redeemed the insane from the cruelty of the moralistic judgment, the fetters unbound by Pinel remaining, let us hope, permanently unloosed; now, through the light shed by psychiatry, she is extending her scientific view so

as to include the criminal, the vagrant and the perverse, and will doubtless advantageously influence penology by gradual rationalization of the code of condemnation. Indeed, the rescue of "sinners" of various types seems to fall within the province of the physician, greatly enlarging the territory in which his functions find exercise. But in rescuing such "sinners," medicine does not approve of their unnecessary multiplication. Medical men, observing among social units, along with the fit, the many that are "notoriously unfit," will be among the most diligent of those who educate to social action that will gradually lessen the numbers of the latter. The results of medical inquiries do not indicate, however, that it is desirable to have a society composed of individuals who are all alike, identical copies of an original pattern, no matter how perfect that pattern might be. For what could be more depressing than the thought of a multitude of human beings with precisely the same natures, possessing the same hereditary qualities in exactly the same degree, all reacting to environmental influences in one stereotyped manner. The very idea is enough to excite horror. No; for the attainment of the highest good in human society diversity rather than identity of form and function is necessary, and for this variety Mendelian heredity fortunately provides. Nor can medicine ever hope definitely to describe every possible combination of germ plasms that will result in native qualities that will ensure physical and social fitness. It has, however, already discovered laws of inheritance that account for at least many instances of physical disease and deformity, and for some of the flagrant examples of social maladjustment and pathological behavior. It has shown us very clearly that society, if it is greatly improved, must give more serious consideration than heretofore to the constitutions of its members as well as to the conditions under which they live.

Medicine, after calling to her aid many auxiliary sciences (biology, psychology, anthropology, sociology), and after prolonged and painstaking research herself, has learned much of the native dispositions common to all men and of their significance to human life. Among these native human inclinations may be mentioned the desire to be physically healthy; to protect and preserve the self and to propagate the kind; the desire to possess; the desire to associate with others; the desire to use the intellect; the desire to create and to enjoy beauty; and the desire for personal conduct that will satisfy conscience. In order that the individual may make the most of life for the self and that he may best serve society, his environment (including his education) should be such as to call forth reactions that will satisfy, in a harmonious and well balanced way, each and all of these fundamental human needs. This does nothing to preclude variety in occupation or in recreation, for in no two individuals are the native dispositions existent in the same order or degree; moreover, in their environment, no two persons are subjected to identical conditions. The possible permutations and combinations are infinite and permit accordingly of infinite variety in both human nature and human conduct for every human being is a unique person; there is and never will be another just like him! This, though a platitude, has ever to be reemphasized.

One of the most important of medical tasks, one that is socially highly significant, is that of advising persons regarding hygienic living. But, it may be asked, how, if no two human beings are alike—and it is desirable for the good of society that they should be unlike—can rules of living that are applicable to all be valid? Must not every man have rules that pertain to him alone? Must he not find, for himself, what diet, what exercise, what work, what association, what recreation and what conduct are best for him? To a certain extent this is true. There can, perhaps, be no universal dietetic-hygienic régime in the concrete. A Yankee in New England does not eat nor need the same diet as the darkey in Mississippi, nor are their actions in other respects identical. What is suitable and essential in habits and morals to the one need not be so to the other.[1] But despite the diversity in human beings, there are such similarities that it is possible, as we all know, to outline certain rules that are, in general, valid conditions for the preservation of bodily health and also certain rules that are, in general, valid conditions for the leading of a socially useful and a spiritually elevated life. In this limited sense, medicine can establish a universal physical and mental hygiene, even though the hygienic adviser in attempting to apply these universal rules to individual lives must know how to adapt them to each person's particular constitution and condition. The hygienic adviser should never forget the uniqueness of each human being. Because of the uniqueness of his hereditary qualities and of his surrounding influences, each person actually requires a special bodily hygiene, special rules for thinking and enjoying, and, yes, even a special code of morality. This is true of what we call normal persons; it is, moreover, increasingly true of the physically diseased, of the mentally disturbed, of the socially maladjusted, of the morally oblique, and of those who are deficient in feeling for beauty.

Who, then, has a larger or a more responsible function than he who undertakes, as the physician is now compelled to do, to act as personal counsellor to people in the conduct of their lives? How extensive should be his knowledge and experience, how great should be his power of imagining himself completely in the place of the person he advises—what has been spoken of as the power "to creep under men's skins"; and with what infinite tact must he be endowed if he is to be able to convince and to persuade! Can there be any doubt of the social significance of the performance of such functions, of the value to society of the performers if they do their work well?

It is upon the general practitioner of medicine, aided by the consultant and the specialist, that the bulk of this work of advising persons of diverse character, and in widely different conditions, as to hygienic living falls. It is to him that the people turn for counsel, especially when disease exists or threatens, but nowadays more and more also, in order that the bodily health and the capacity to work may be preserved, that mental functions may be exercised freely and that conduct may be conducive to personal and public welfare. He it is who watches the digestive, the circulatory, the respiratory, the hematopoietic, the urogenital, the locomotor, the nervous, the

[1] Paulsen, F., *A System of Ethics*. English translation by F. Thilly, New York, 1908.

endocrine and the metabolic functions, and determines when therapeutic intervention is necessary. He educates his patients to avoid everything that impairs these functions and to do everything that will strengthen and harmonize them. He warns when necessary against caprice in eating, against undereating, against gluttony, against the misuse of alcohol or tobacco. He teaches the importance of a balanced food ration of appropriate caloric content, the necessity of considering health as well as fashion in clothing, and the value for health, happiness and efficiency of a well arranged program of work, of leisure, and of recreation. He tries to stimulate the idler to fruitful industry, the spendthrift to frugality and the miser to liberality, for idleness, extravagance and avarice are vices that are both injurious to the person and harmful to social life. To those who have secured incomes that more than suffice for their biological needs, he points out the dangers of hypertrophy of the possessive instincts and encourages the promotion of the intellectual, social, esthetic and ethical interests. Indeed, the physician can often be most helpful to his patients in guiding them to sources of truth, to desirable companionship, to participation in community efforts, to the enjoyment of the beautiful in art and literature and to worthy conduct that conforms to more ideal standards. There are those who maintain that the domain of the physician does not extend beyond the body of the patient and its perfection. I cannot agree with them, but were we to accept their view, it might still be urged that beauty and grace in the body can be attained only through proper cultivation of the mind and spirit. Selfmastery is essential to bodily grace, and only when the soul is good and beautiful can the highest type of bodily beauty be realized. Moreover, in order that health of mind and body may be maintained, it is essential that the whole personality of the patient be developed in an allround and proportionate manner. Undue suppression of the sex interests, of the possessive interests, of the intellectual interests, of the social interests, of the interests in the creation and appreciation of the beautiful, or of the interests in right living, will react unfavorably upon either bodily or mental health, or both. Thus attention to all these interests must obviously fall within the province of the physician, and he who conscientiously strives to perform his duties to his patients does not neglect them. In lending his aid, however, to his patient in attaining to the realization of his total self, the physician will avoid making him too subject to his counsellor. The aim of the best hygienic educator will always be to lead his pupil to selfreliance and to independent selfdetermination.

Thus far I have referred chiefly to the social service rendered by medical investigators and medical practitioners. If time permitted, it would be interesting to review also the meaning and value to society of the activities of medical authors, medical teachers, medical organizers and medical executives, including the directors of hospitals, sanitaria and asylums, and public health officers. But I must have some regard for the limits of your patience.

I cannot, however, forbear some comment upon the importance to society of the activities of certain members of our profession who may be designated, perhaps, medical statesmen. By these I mean those medical men of large vision who, better than their fellows, see the importance of the promotion of the science and art of medicine for the progress of civilization, who devise new plans for improving the conditions of practice, teaching and research, and who are helpful in passing better laws and in establishing better institutions, educational and political, for rendering the state needed work of physicians and scientists more fruitful and more secure. These men are never ignobly content with the past or with contemporary achievements of the profession. They are the shakers of creeds, the questioners of dogmas, and the critical surveyors of received traditions. They see ever new goals that should be sought and they confront us with new problems—physical, mental, educational, industrial, social, international—that medicine can help to solve. They stimulate our interest and the interest of intelligent laymen in these projects; they prepare the plans for the work, and they find the men and the money necessary for these new ventures.

And finally, the examples in living set by medical men themselves can scarcely be without their value for society. Though they have their faults and many of the common human failings, medical men, through their knowledge and training, should be better able than the average man to order their own lives well, and, on the whole, I believe that they do. When they take care of their own health, marry happily, train their children sensibly, attain to economic independence, attend to their social duties, keep their intellectual interests alive, show their appreciation of the beautiful things in Nature and in the work of man and respect the rights of others, they become artists in life and their mode of living is worthy of social esteem. For example is better than precept and lends force to precept. Those whose business it is to inculcate the principles of hygiene—physical, mental or moral—will have a larger success if their own lives are not too discordant with their teachings. In the worthy satisfaction of his own fundamental needs, exhibiting restraint without undue restriction, and illustrating moderation that has no taint of meanness, each physician may strive to exemplify hygienic living in the larger sense and so further contribute to the social significance of his profession.

A distinguished Canadian jurist once remarked to me that any man might well be proud who belonged to a profession that deserved the high tribute paid to it by Oliver Wendell Holmes. The lines he referred to may be familiar to some of you, and perhaps I cannot do better than to close with them: "Charity," said he, "is the eminent virtue of the medical profession. Show me the garret or the cellar which its messengers do not penetrate; tell me of the pestilence which its heroes have not braved in their errands of mercy; name to me the young practitioner who is not ready to be the servant of servants in the cause of humanity, or the old one whose counsel is not ready for him in his perplexities, and I will expatiate upon the claims of a virtue which I am content to leave you to learn from those who have gone before you, and whose footprints you will find in the path to every haunt of stricken humanity."

1035 North Calvert Street.

Choice of Operation for Inguinal Hernia

EDMUND ANDREWS, M.D.,
Chicago

"How do you do your hernias?" Only too frequently is the surgeon asked this question. The usual answer is, "So and so's operation," and the inquirer is quite satisfied. The real truth is that such a query should take an hour to answer. Hernia is not a simple disease. Its pathology is multiform and varied. No two are really alike. Consider the absurdity of classifying a small direct bubonocele, a sliding hernia and a large oblique scrotal hernia as one disease, and having but one surgical procedure to suit them all. That is exactly what is done in most clinics, and I feel sure that here lies the reason for the unduly large number of recurrences. Careful study of followup reports show that about six to eight per cent. recur. If operations in children are included the rate is considerably less. The true scientific surgeon should have not one or two, but a large series of operative measures at his finger tips devised, not for hernias in any broad sense, but to deal with each feature of the pathology as it is encountered.

Just exactly what is this pathology? Certain broader features are diagnosed before operation, the size, type, condition of the external ring, and if this ring is large, the examining finger can often acquire a little information as to the condition of the floor of the canal. However, the real pathological diagnosis is made only after the canal is laid open. We must consider:

1. *The sac.*—There can no longer be any question as to the etiology of oblique hernia. It can never occur unless there is a failure of obliteration of the processus vaginalis. The sac is preformed. Russell (1) has recently given an admirable summary of the evidence for this, as have Coley and others (2).

2. *Weakness of the endoabdominal fascia.*—The real internal ring is a hole in this fascia. This is the point where strangulation practically always occurs. There may be a diffuse thinning of this structure, or it may simply have too large a gap in it for the exit of the cord. Whether this is a cause or a result of the hernia is doubtful and has little bearing on the treatment.

3. *Conjoined tendon deficiency.*—The conjoined tendon is deficient or even absent in a majority of men with hernia. It is a commonplace to surgeons that they insert the inner row of stitches in red muscle, not into a tendon. It is also commonplace that this muscle does not insert on to the pubis behind the external ring, as one finds in the dissecting room. It inserts on to the lateral border of the rectus sheath at a variable distance up from the pubis. Polya (3) measured the amount of rectus thus bordering the canal in one hundred cases and his results are given in the following table:

CASES	LENGTH OF RECTUS	CASES	LENGTH OF RECTUS
1	0	17	4
7	1	9	5
31	2	5	6
28	3	2	7

Ferguson (4) made similar measurements as to the origin of the lower fibres and found that the same was true of the lateral end of the canal. These points constitute the real pathological anatomy of hernia. They should be looked for, noted, and only then can the choice of surgical procedure be made. These procedures may be roughly classified as follows:

1. SIMPLE SAC REMOVAL

In many cases it appears that the sac is the only pathology; all the other structures in the canal are found to be normal. In that case it is surely logical to say that the removal of the sac is all the operation indicated, and anything further is superfluous. As I shall attempt to show later, any further surgery may be positively harmful. In recent years a number of operators have been courageous enough to put this theory into practice, and the results have amply warranted the innovation. Hull (5), in charge of a large hernia service in the British Army during the war, did over five hundred such operations and said he had fewer recurrences than by other technics. He worked under local anesthesia, making an inch long incision over the internal ring, split the aponeurosis, made a high sac removal and closed the wound with a single stitch. Hoffman (6) did a large number and had but two per cent. recurrences. Sulzer (7) traced fifty and found no recurrences. This procedure has gained considerable favor in other German clinics. I have used it myself in a number of cases with apparently good results. I believe that this operation is indicated in the following classes of cases: a. Small recently acquired hernias, especially those encountered in military or industrial work, where they are discovered very early during routine physical examinations. b. Many hernias in children. c. The socalled phantom operations, the prophylactic operation on the well side of the young man with a congenital hernia on the other. In almost every one of these that I have done, I have been rewarded by finding a well developed, though empty sac on the apparently normal side.

2. BASSINI OPERATION

The general features of this technic need no description here. In brief, it consists of opening the canal, high sac excision, suture of the conjoined tendon to the inguinal ligament and closure. Some details, however, are important.

Completeness of the excision of the sac is not a guarantee that it has been done correctly. There is a wrong and a right way to do it. It is very easy to make a high sac removal and still leave a gaping hole in the endoabdominal fascia. We must carry our dissection so high that the transfixion and ligature include not only the peritoneum but this important fascia as well (Figs. 1 and 2). This structure can usually be recognized as a white opaque layer, quite distinct from the thin, transparent, glistening serosa. In many cases this cannot be done by the

ordinary methods. Torsion of the empty sac may help. Most surgeons give up here. If these methods fail nothing else is attempted. There are numerous methods of really closing this hole and they deserve wider recognition, as this is the crucial point in the whole operation. An old way I have found useful is to split the sac in two right down to its neck, lay the flaps wide open and then close the neck by a running suture exactly as one would in any other laparotomy wound. This is of special value in the type of cases in which the neck of the sac is very large, and not round but long and slit-like. In other cases careful dissection will expose the hole in this important fascia and it can be closed with a running suture. However, each case is a problem in itself. Pitzman's (9) suggestion of sewing the neck of the sac together with the traversalis fascia to Poupart's ligament is often of value. Opening the abdomen an inch above the canal and closing the ring from within (10), is another maneuvre which has distinct advantages. In every case in in which this inner ring closure has been difficult and where any doubt as to its completeness exists, the neck of the sac should be transplanted upward and outward and fixed to the abdominal wall away from the weak spot. This can be done very quickly by simply attaching curved needles on each end of the sac ligatures and bringing them out through the raised internal oblique as far as possible from the internal ring (Fig. 3).

It must be borne in mind that the entire success of the Bassini operation depends on the healing of the internal oblique muscle on Poupart's ligament. As stated above it is a fleshy red muscle, not a tendon. Much doubt has arisen of late if this really ever occurs. Certainly such a condition is rarely encountered in pathology. The only normal findings of such a condition are at the musculotendinous junctions. The object is achieved here by an exceedingly complicated and delicate structure. Seelig (11) discusses this point and reports some very interesting experimental observations. He was unable to achieve such a union in animals. The stitches promptly pulled through even if little tension existed. Permanent material yielded no better results than catgut sutures. McNealy (12) has noted a number of postmortem examinations of cadavers with old herniotomy scars. In no instance, whether the operation had been successful or not, had the red muscle remained attached to Poupart's ligament. Following the Andrews operations the external oblique had remained in place but the internal had pulled loose. Lameris (13) made similar observations. Oudenarde (14), after studying a large series of recurrent hernias, arrived at the same conclusions, and his very elaborate article closed with the following words in capital letters: *Le Bassini doit etre abandonnée.* I am not prepared to go quite that far yet but I do believe that its use is very limited. It does, however, afford a better means of making a complete sac removal than Hull's method, and I still use it in small hernias but am now very careful to make the stitches very, very loose. One fact is very disturbing to me. That is that so many oblique hernias recur in the direct form, at the inner end of the canal. I can give no other interpretation than that this means that the stitches we put in in this region have actually done harm instead of good.

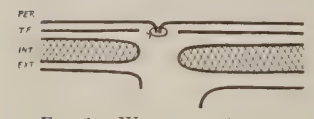

FIG. 1.—Wrong way to remove sac; peritoneum closed but hole in transversalis fascia left untouched.

FIG. 2.—Right way to remove sac; edges of transversalis fascia included in ligature.

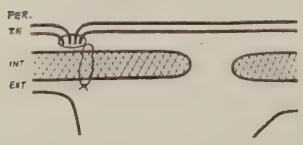

FIG. 3.—Stump of sac fastened to abdominal wall away from internal ring.

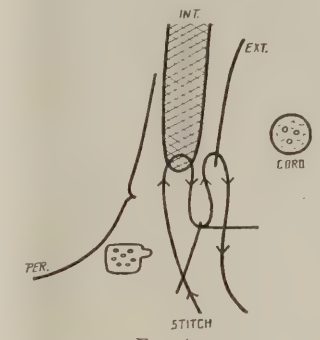

FIG. 4.

FIG. 5.

FIG. 4.—Stitch used in Andrews operation; cord lifted, stitch begins in Scarpa's triangle, goes under Poupart's ligament, takes bite of internal oblique, back through sharp shelving edge of Poupart's, then to external oblique, and out into Scarpa's triangle through lower fragment of external oblique aponeurosis.

FIG. 5.—Domeshaped bulging of direct hernia.

3. ANDREWS OPERATION (15)

This also is too well known to require description here. It consists, in a word, in sewing the internal and external oblique to Poupart's underneath the cord, replacing the cord in its new bed and making a roof for the canal with the left over lower flap of the external oblique aponeurosis. I now wish to describe a special suture used for this purpose (Fig. 4). It will be noted that all the knots lie outside the inguinal canal. This permits one to use much larger suture material and it has been the custom to use the heaviest kangaroo tendon. This reinforcing of the floor of the canal should be used in every case in which there is any evidence of weakness of the endoabdominal fascia, or if there is any muscular deficiency. This of course will include most old hernias and all large ones.

Here again we must not be satisfied with any routine, but must arrange and plan our structures to fit. This cannot be done in advance any more than a tailor could make a suit without taking measurements. One is often asked if he takes any stitches above the cord. This most certainly should be done if there is any gaping there. I make it a practice, however, if such a gap exists, to attempt to pull the cord outward and put the stitches under it. This actually angulates the cord, making a sharp upward kink in it. It also lengthens the canal, a most desirable thing. I have never seen any interference with the circulation after such a procedure.

Many other slight modifications are of value in suitable cases. Sometimes the edge of the external

oblique after being sutured to Poupart's, stands up in a series of ruffles between the stitches. Here, a small running stitch is needed to secure adequate approximation. If the cord is very bulky the Torek (16) method should be used. He divided it into two segments, and brought them through the floor of the canal separately. It is surely better to have two very small holes than one large one.

4. USE OF RECTUS

Nearly every series of recurrent hernias reported shows at least half of the recurrences near the pubic spine. This is our weakest point. In our ordinary methods of operating it is at this point that the tension is greatest. If the internal oblique inserts high up on the rectus sheath, and this point is pulled down and sutured to Poupart's ligament, the tension will be too great to permit healing. For this reason the rectus itself should be utilized in the closure in a far larger number of cases than is done at present. The sheath may be split and the actual red muscle pulled over to reinforce this weak spot (17), but this is open to the same objections as the Bassini, as stated above. The Halsted technic (18) for the use of the rectus sheath is far the best. A flap of this strong fascia is turned outward and produces the best possible covering for this danger spot. This step should be added to the Andrews operation in, a, all very large hernias; b, all hernias in which the conjoined tendon deficiency is extreme, and c, all direct hernias. I now use this additional safeguard about one quarter of the time.

5. DIRECT HERNIAS

The vast majority of direct hernias show little tendency towards growth. They are due to an enormous deficiency in the conjoined tendon and to a marked diffuse weakness of the endoabdominal fascia (Fig. 5). The sac is domeshaped and has no neck, and for this reason strangulation is almost unknown. The sac of an indirect hernia may lead preformed out through the external ring or its smallness and fingerlike shape favor its exit. Conditions are utterly different in the direct type. The massive wide sac has little tendency to protrude from the canal. In view of these facts I regard a direct hernia, not as a disease, but as an anomaly, perhaps comparable to potbelly. It is not in itself an indication for surgery. It is perfectly harmless in the vast majority of cases. Furthermore, it is far more amenable to truss management than other types.

Let us examine recurrence rate of direct hernia.

RECURRENCES IN DIRECT HERNIA[1]

Author	*Cases*	*Recurrences*	*Percentage*
Lameris (13)	102	29	28.4
Davis (19)	88	13	15.9
Erdmann (20)	383	52	16.6
Russell (1)	14	3	14.3
Taylor (21)	47	14	29.8
Average	634	111	17.7

[1]These figures are from some of our best clinics.

We have then a disease (socalled) which kills or incapacitates very rarely and in which one fifth of our operations are failures. Is it not reasonable, then, to say that we should operate only for special indications? These are growth or pain. Other conditions should be left alone and the patients simply reassured of the harmlessness of the condition.

6. CORD TRANSPLANTATION

This term, as it is now used, is a decided misnomer. To say that it is transplanting the cord to close the internal oblique beneath it is flying in the face of most elementary and evident anatomical facts. While the position of the cord in relation to the muscles varies within very wide limits, it surely has never been known to lie *under* the muscle. The operation of closing the internal oblique over the cord was devised by Ferguson (4) about twenty-five years ago. It never achieved much popularity except in the region under his own personal influence, and is almost unknown in Europe. Every series of cases followed has shown a higher percentage of recurrences by this method. It not only destroys the obliquity of the inguinal canal, by placing the internal ring directly under the external one, but worse yet, it leaves the weak spot next to the pubic spine. There are a few kinds of cases, however, where this operation is indicated. They are, a, in sliding hernias. These have a very high recurrence rate and practically always recur at the upper end of the canal, and the Ferguson operation leaves no weak spot here. b. In certain cases of cryptorchidism. If there is much difficulty in getting the testis into the scrotum on account of the shortness of the cord, a little may be gained by sewing the cord underneath.

The advantage of this procedure is its ease and simplicity. There is no doubt that crowding the cord downward and making the closure over it offers less difficulty than any other known method of herniotomy, and to this fact I attribute the persistence of this inferior method.

7. PLASTIC METHODS

Finally, it cannot be too strongly emphasized that herniotomy is a plastic operation. Its success depends on the union of structures which are not normally adherent. All the laws and all the limitations of plastic surgery apply equally to this class of work. The first law of plastic surgery is that no tension can be tolerated. That is a principle which no matter how unpleasant must be faced in the surgery of hernia. Any hole in the abdominal wall can be pulled together by the use of powerful tension, but just as surely as this is done the two structures are going gradually to pull apart again. Both theory and the results of our practice show this. Let us, therefore, not dodge the issue by drawing a curtain of skin over our clumsy efforts. If our stitches are too tight, cut them and fill the hole with a fascial transplant. Small transplants of this sort heal readily and their loss by sloughing is extremely rare. They can be tailored to fit the defect and made large enough to avoid any tension.

It is only by careful attention to detail, the use of a wide variety of surgical procedures, conservatism in simple cases, and radical work in hard ones, that we can expect to reduce the percentage of failures, which is bringing the operation of herniotomy into disrepute. This percentage is from six to eight, and when one considers the enormous number of patients operated on each year, there must be a multitude of dissatisfied patients.

The Importance of the Direct Examination of Bile in the Diagnosis of Gallbladder Lesions*

MAX EINHORN, M.D.,
New York

(*Concluded from page 13*)

On January 17, 1924, the patient was operated upon by Dr. De Witt Stetton. The findings were as follows:

There was a thickened whitish gallbladder with adhesions at the neck of the duodenum. No calculi could be palpated in the gallbladder, ducts or at the papilla. The surface of the right lobe of the liver adjacent to the gallbladder showed a definite inflammatory thickening of the capsule. The foramen of Winslow was patent. The pancreas was not indurated. The appendix was thickened and elongated and located below and to the inner side of the cecum. The distal half was free, but the proximal half bound down by dense adhesions. A cholecystectomy without drainage and an appendectomy were performed. The gallbladder was somewhat thickened, the mucous membrane distinctly papillary in type (beginning strawberry gallbladder). The contained bile was thick, somewhat turbid and dark green in color. The appendix was elongated, thickened, with hypertrophic mucous membrane and submucous hemorrhages. Microscopic examination (Dr. Bullock) showed chronic catarrhal cholecystitis, and acute and chronic appendicitis.

In contradistinction to these three cases of severe cholecystitis without gallstones, a case may be described having sandlike particles in the bile, with a crystal formation smilar to that in the cases cited, in which real stones were found. The history is as follows:

Case IV.—Mrs. A. F. about twelve years ago had an attack of severe sharp pain in the right side of the epigastrium, beginning suddenly and without apparent cause, in the morning, accompanied by nausea and vomiting. This lasted only an hour, and several months elapsed before she had a similar attack. Gradually the attacks became more frequent and more severe, the pain spreading around to the back and up to the shoulder blade on the right side. After one attack of vomiting the cramps in the shoulders and arms were so severe that she was unable to move them. She stated that with these attacks she would usually have a chill (hot and cold sensations). Once, some eight or nine years ago, she became jaundiced for three or four days. She had always been constipated. Had not noticed blood in the stools, nor clay colored stools. Her vomitus was never bloody but was often green and bitter. About six years ago she started taking some patent medicine and stated that she had been absolutely free from her attacks for four years. After the birth of twins a year and a half ago, her trouble started again. She had a severe attack the night the twins were born, and another the following night. From then on she had had attacks at almost weekly intervals, each one more severe than the last. Lately they had occurred twice a week. She said that during the last nine years she had taken morphine during every attack. Atropine was given to her during the last few months. Belching of gas always accompanied an attack.

Her gastric contents showed a high acidity, totaling 86; the string test showed a blood stain at twenty-two and one half inches from the lips; the bile was turbid, containing blackish sandlike concretions, showing microscopically cholesterin, calcium bilirubin, and "bunch berry" crystals. The patient had another attack of probable gallbladder colic while undergoing the examinations, requiring morphine.

An operation was decided upon and was performed by Dr. De Witt Stetton. The gallgladder was found slightly adherent to the duodenum and contained six stones each about the size of a bean, yellowish in appearance. The scrapings from the surface of one of these stones consisted principally of amber looking "bunch berry" crystals. (Fig. 44.)

In conjunction with these remarks regarding diagnosis a few words on treatment will not be superfluous. Everyone is acquainted with the general principles of treatment in most gallbladder lesions. These are rest, frequent small meals, plenty of fluids, regulation of the bowels, and medicaments or other means to increase the flow of bile. Mineral waters, especially those having laxative qualities, are of benefit. Some clinicians think highly of the salicylates; others recommend instead glycerine or olive oil; still others ascribe great value to the method of draining the bile through a duodenal tube, especially after magnesium sulphate or similar substances had been given, increasing the flow of bile. In a number of mild gallbladder lesions, similar régimes will accomplish the desired effect.

With regard to diet, I am not in favor of restricting the variety of foods too greatly. This I say because a great many physicians forbid all food substances containing much cholesterin, such as eggs, fish, etc. While cholesterin is found in gallstones, their formation is not always due to the abundance of cholesterin in the food but rather to an abnormal state of the bile.

In an exceptional number of instances of gallstone colic in which an operation appears demanded, nature can yet accomplish a cure without resort to surgery. This is effected by the formation first of adhesions between the gallbladder or biliary tract and duodenum, and then by the breaking through between the gallbladder wall or the walls of the ducts into the duodenum (without leakage into the peritoneal cavity), creating an opening for the passage of the stone so that it can be passed through the intestine. Such an occurrence took place in the case

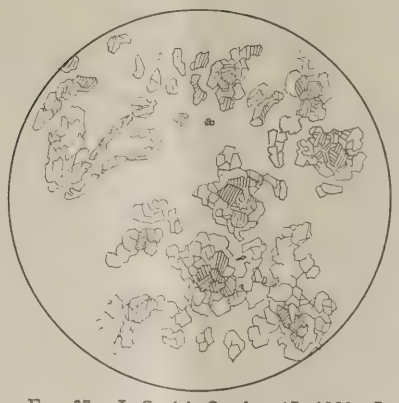

FIG. 37.—J. S. (*c*) October 17, 1923. In the bile cholesterin and calcium bilirubin crystals.

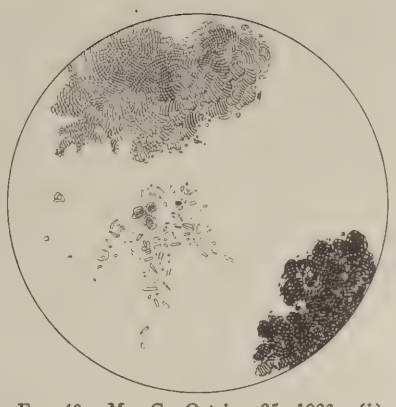

FIG. 40.—Mr. G. October 25, 1923. (*b*) High magnification. Bunchberry crystals.

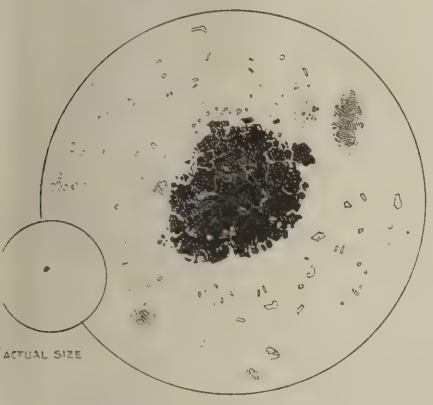

FIG. 39.—Mr. G. (*a*) October 25, 1923. Low magnification. Bile dark yellow, greenish tinge. Black sandlike particles containing calcium bilirubin and cholesterin crystals.

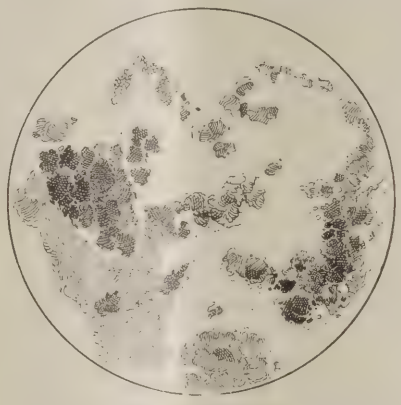

FIG. 38.—J. S. (*d*) November 2, 1923. At the operation a pinhead size concretion was found in the bile flowing out of the choledochus showing the bunchberry appearance.

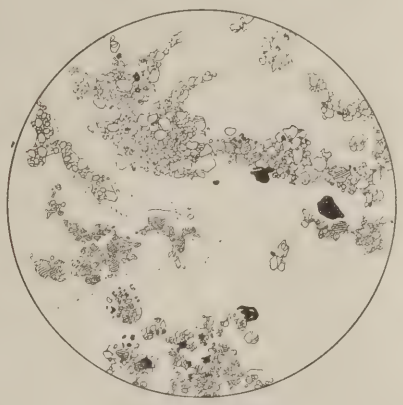

FIG. 41.—Mr. B. December 18, 1923. Bile dark yellow, turbid; blackish sandlike particles containing cholesterin and bunchberry crystals. (No operation.)

FIG. 42.—G. November 27, 1923. Bile light yellow, very turbid. Blackish particles; black crystals, some cholesterin and mucus.

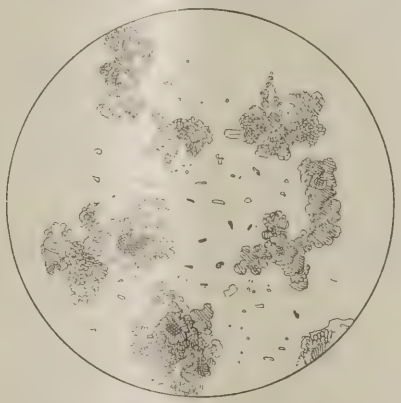

FIG. 43.—F. October 9, 1923. Dark brown yellow, very turbid; calcium bilirubin and cholesterin crystals; mucus.

FIG. 44.—Mrs. F. January 14, 1924. Scraping gallstones found at operation; cholesterin, bunchberry and rhomboid crystals.

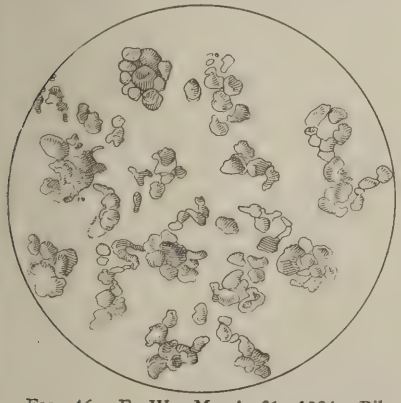

FIG. 46.—F. W. March 31, 1924. Bile turbid, containing sandlike particles, consisting of bunchberry crystals.

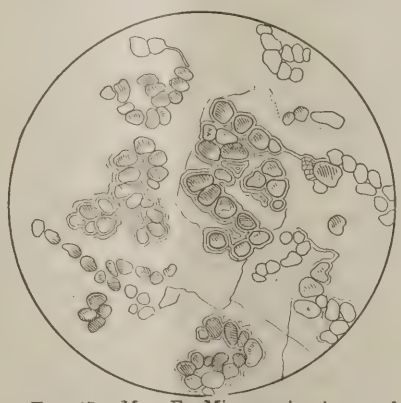

FIG. 47.—Mrs. F. Microscopic picture of scrapings from gallstones, removed by operation on Jan. 14, 1924. Bunchberry crystals.

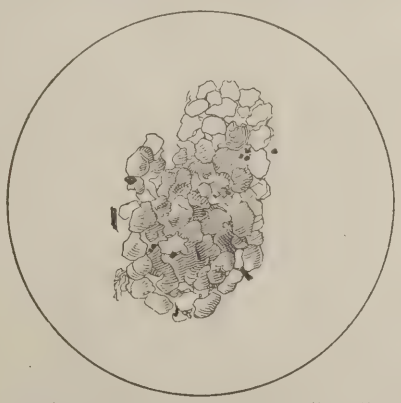

FIG. 48.—K. March 6, 1924. Bile yellow brown, turbid. Brownish particle containing bunchberry crystals.

of Mrs. M. while she was under observation in my care in the Lenox Hill Hospital. Her history is as follows:

Case V.—October 23, 1922: Mrs. M., aged about forty-six, complained of pain in the right epigastrium for the past year. She stated that she had been troubled with bilious attacks for the past ten years, accompanied with much vomiting of bile. She suffered no great amount of pain until a year ago when pain in the right epigastrium became a prominent symptom. The patient had been free from these attacks of pain for many months. The pain was of a dull gnawing character, beginning just after eating; relieved a great deal by bicarbonate of soda. The pain starts in the epigastrium, extending gradually around to the back and up to the shoulder.

Blood examination: white blood cells 6,800; polymorphonuclears 72 per cent; lymphocytes 24 per cent.; mononuclears 4 per cent; red blood cells 5,400,000; hemoglobin 90 per cent. The gastric contents showed: hydrochloric acid 5; total acidity 65. String test: blood stain at 23 inches; bile from 24 inches to end.

Examination of the bile showed it to be very turbid, containing many red blood corpuscles, pus, cholesterin, and bilirubin crystals.

X ray examination of the teeth showed extensive pyorrhoea. X ray examination of the stomach: Stomach and intestines appeared normal, except that pyloric end was held permanently to right notch in duodenum produced by distended gallbladder, sensitive area over gallbladder region, hepatic flexure of colon adherent to gallbladder region. Diagnosis: Cholecystitis; pyloric end of stomach adherent to hepatic flexure of colon. No gallstones visible. I am indebted to Dr. Gibbons of Scranton, Pa., for this x ray report and for referring patient to me.

The examination of the bile showed that there was some bleeding going on in the duodenum, rather more than is usual with ulcers. In the stool passed a few hours later, which was sifted, was found a gallstone about the size of a medium sized acorn, which relieved the symptoms. The perforation was evidenced by the bleeding in the duodenum at the time of the passage of the stone. The patient has remained apparently well ever since (for I have not heard from her).

Unfortunately, we cannot always count upon this favorable occurrence, and it is usually necessary to recommend an operation in suitable cases.

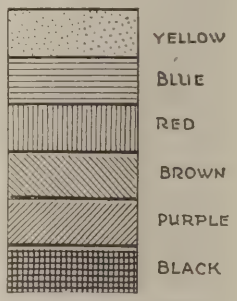

Fig. 45.—The colors in most of the figures are indicated by the different shadings shown above.

INDICATIONS FOR SURGERY

1. Severe abdominal colic due to gallbladder lesion, accompanied by temperature, leucocytosis, and a high polymorphonuclear count.

2. Severe biliary colic, necessitating hypodermic injections of morphine, accompanied by chills and fever, or occurring frequently so that there is danger of acquiring the morphine habit.

3. Whenever empyema of the gallbladder is suspected.

4. When malignancy cannot be readily eliminated.

In short, it may be said that patients should be operated upon only when there are severe subjective symptoms present in connection with the objective findings, and prolonged medical treatment proving of no avail.

Kidney Function in Osteitis Deformans

Report of a Case

FRANCIS J. SCULLY, M.D.,
Hot Springs, Ark.

Impairment of the kidney function in advanced osteitis deformans (Paget's disease) appears to be a rather constant finding. While a review of the literature shows this condition to be present in most cases, no special notice has been taken of it. In the majority of instances it has been mentioned only incidentally in the case reports. The following advanced case of osteitis deformans with typical changes in the skeleton presents a rather marked impairment in this respect.

Case.—J. D., a man, aged seventy-seven, seen October 17, 1922, complained of attacks of palpitation lasting from ten to twenty minutes. There was no pain associated with the attack, but the rapid beating of the heart disturbed him and he felt weak. These attacks had been present for several years.

For the past five years the patient had been using crutches on account of the increasing curvature of his legs. He was able to walk without this aid but not so rapidly. He was able to get up and down without difficulty. Although the deformity of the skeleton was marked, the patient did not complain of any discomfort from it except the awkwardness in walking. The condition had its onset in 1905 when he noted pains in the legs. The next year bowing of both tibiæ developed, starting first in the right tibia, in which it has always continued more marked. At that time he was sixty years of age, and had retired from his business in a bank where he had been on his feet during most of the day. In 1916 he noted that his head began to get larger. The increase in size had been gradual, so that the size of his hats had increased from 6⅞ to over 8¼ which he was wearing. With the increasing bowing of his legs he had lost six inches in height. He had noted no pains since the onset except occasional aching in the shoul-

ders and arms. For the past ten years his vision and hearing had shown increasing impairment.

The patient's father died of stomach trouble, and the mother from an abscess in the abdomen. One sister who died at sixty-five years of age had the same disease of the skeleton, but with more marked deformities. She had had the disease for many years, and became totally deaf before she died. One brother also had a very large head, but no noticeable deformity of the legs.

Fig. 1.—Patient with osteitis deformans showing enlargement of skull with prominent overhanging brows.

The patient had been always healthy and had had no acute illness in his life except an otitis media at sixty-two years of age. Since the onset of the osteitis a rather marked arteriosclerosis had developed, and accompanying this an increase in the blood pressure with cardiac hypertrophy was noted. Several years ago there were repeated retinal hemorrhages in the right eye. Albumin had been present in the urine for the past six years.

Examination showed the patient to be in fairly good health considering his advanced age. As a result of the osteitis marked deformity of the skeleton was present. Probably the most striking feature was the enlargement of the head with the prominence of the parietal and frontal eminences. The forehead was large and the brow overhanging (Fig. 1). Both clavicles were prominent, thickened, and sharply bent. The spine showed very little curvature, and was not rigid. The iliac crests were large and flaring. On standing the deformity of the legs was particularly marked. Both femurs were thickened and bowed outward, and both tibiæ were markedly increased in size and bowed anteriorly as well as outward. When standing with the feet together the internal condyles of the femurs were fourteen centimetres apart (Fig. 2). The circumference of the head was sixty-four centimetres, and the distance from ear to ear over the vertex was thirty-six centimetres. The patient's height was five feet three inches.

Associated with these deformities of the bones, there was a marked sclerosis of the peripheral vessels. The pulse was irregular in rate and force, the blood pressure 154 systolic, 95 diastolic. The cardiac dullness was increased, the left border being an inch beyond the nipple. A loud systolic murmur was heard over the entire precordium, but was best heard at the aortic base. No abnormal neurological findings were present except the impairment in vision and hearing. Ophthalmoscopic examination showed both discs to be somewhat hazy in outline, and the retina to be pale. The vessels showed considerable sclerosis, and in the right eye there was an old choroiditis with evidences of old hemorrhages.

Laboratory examination of the urine showed a heavy trace of albumin and many hyaline casts. The volume for twenty-four hours was 960 cubic centimetres, the specific gravity 1.016 and the reaction acid. A kidney function test showed an excretion of ten per cent. of phenolsulphonephthalein in two hours on one observation and fifteen per cent. on a second observation. Chemical examination of the blood (1) on November 10th gave 26.5 mg.of urea, 2.8 mg. of uric acid, 56 mg. of nonprotein nitrogen and 1.4 mg. of creatinin to the hundred cubic centimetres. On November 25th the tests showed 4.0 mg. of uric acid and 1.02 mg. of creatinin, and on December 12th 15.5 mg. of urea, 4.5 mg. of uric acid, 46.2 mg. of nonprotein nitrogen and 1.8 mg. of creatinin to the hundred cubic centimetres. A blood count showed 90 per cent. hemoglobin, 5,120,000 red cells and 7,000 white cells. The Wassermann test was negative.

A röntgenogram of the skull showed marked involvement. The normal dense appearance of the calvarium was entirely lacking, being replaced by a motheaten rarefied structure. The skull varied in thickness from one to one and a half inches. Similar rarefication was noted in the pelvic bones, the vertebræ, the tibiæ, femurs and clavicles. The large arteries of the extremities showed extreme calcification being outlined for their entire length.

COMMENT

Although the urine shows nothing distinctive in osteitis deformans, not infrequently albumin is found. Generally only a faint trace is noted. Accompanying this are found hyaline casts and occasionally pus cells. The specific gravity varies from 1.014 to 1.024. The presence of albumin has been reported by Fitz (2), Lyons (3), Stahl (4), Stivelman (5), Carman and Carrick (6) (twelve cases), Ely (7) (two cases), Gaenslen (8), Goldstein (9) (seven cases), and many others. Hyaline casts were noted by Lyons, Gaenslen, and Goldstein. Epithelial and granular casts were reported by Stahl. Carman and Carrick noted occasional pus cells in four cases and occasional red cells in one case. Negative findings were reported in one case by Lewin (10), and in three cases by Carman and Carrick. In general the urinary findings are those of a chronic interstitial nephritis.

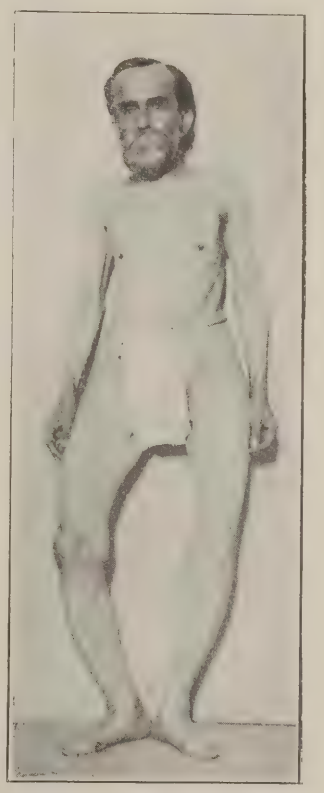

Fig. 2.—Patient with osteitis deformans showing marked bowing of legs.

The excretion of phenolsulphonephthalein was rather low, being only ten per cent. in two hours on one observation, and fifteen per cent. on the second

test. This would indicate considerable damage to the kidney tissue, and some evidence of it could be expected in the retention of protein waste products which was found to be true. Only one report in the literature, that of Carman and Carrick, gave the results of this test. They reported the excretion normal in two cases and in a third thirty per cent. in two hours.

Chemical examination of the blood showed only slight retention of protein waste products. This was probably due to the rigid diet and strict attention to the elimination. The urea is slightly above the normal of fifteen mg. to the hundred c. c., but is not a sufficient increase to be significant in itself. However, the finding of 4.5 mg. of uric acid as compared with the normal of two mg. to the hundred c. c., would indicate an early diminution in the functional capacity of the kidneys. Goldstein reported similar results in two cases, in one the urea was twenty-five mg. and the creatinin 1.3 mg., and in the other the urea was twenty-five mg. and the uric acid 6.6 mg. to the hundred c. c. Such slight increases in uric acid and urea are seen in the early stages of chronic interstitial nephritis and in arteriosclerotic changes of moderate degree in the kidneys.

Postmortem studies of the kidneys in osteitis deformans have been reported by Higbee and Ellis (11), Cone (12), and Goldstein. More or less marked interstitial sclerosis was present in each case. This would be in agreement with the clinical findings detailed above.

It is doubtful if the impairment in the kidney function has any etiological significance in the development of the bone changes. It appears more likely that the kidney changes are secondary, or at least an associated condition. It is possible that the causative factor producing the bone changes also affects the kidney so that sclerosis of an interstitial type results. With the characteristic thickening of the arteries in this disease due to the marked deposit of lime salts in the walls, it seems probable that similar arteriosclerotic changes occur in the kidney vessels and that the clinical findings of impaired kidney function could be explained on that basis.

Phlebitis and Thrombophlebitis Migrans*

JOSEPH HARKAVY, M.D.,

New York.

Phlebitis migrans is an inflammatory affection of the veins the outstanding feature of which, as its name suggests, is its migratory character. Clinically, this condition is distinguished by the following: 1. A tendency to involve superficial veins, especially of the upper or lower extremities, notably the internal or external saphenous, not infrequently also those of the trunk and chest. 2. A decidedly segmental distribution with healthy vein intervening. 3. A progressive spread which is usually accompanied by moderate fever. 4. A lesion having the appearance of an erythematous fusiform nodular mass about two to four cm. in length and one to two cm. in diameter, which is sensitive to touch. The overlying skin may be distinctly edematous, although at times pale and free from signs of inflammation. Pathologically, the inflammation may be confined to outer or middle coats of the vein, or both, in which case no impairment of the lumen occurs, and after complete subsidence of the inflammation no signs of previous involvement need be manifest. On the other hand, the outer, middle and inner coats may be affected, under which circumstances thrombosis may supervene with closure of the lumen. When such is the case, a hard cordlike thickening of the vein remains after the acute stage has subsided, unless canalization of the thrombus occurs. While in ordinary migrating phlebitis, which is confined to the superficial veins, no edema is usually seen, the occurrence of edema of the extremity involved is not infrequent if the thrombosis is sufficiently extensive and the affected vein is of considerable importance.

Whether thrombosis has or has not occurred, only the clinical course can disclose. The outward appearance of the vein, in the initial stages at least, is identical in both instances. In the strictly pathological sense, those cases in which thrombosis does not develop are called phlebitis migrans, and those which go on to occlusion should be called thrombophlebitis migrans.

PHLEBITIS MIGRANS.

Cases of phlebitis migrans as such are scattered through the literature associated with a variety of clinical conditions. Trauma, rheumatic fever, gout, toxic or cachectic states are not infrequently accompanied by this condition. Whether or not the phlebitis is caused by the same toxins which are responsible for the original disease, it is impossible to say. In rheumatic fever, the well known vulnerability of the cardiovascular system may perhaps account for the venous involvement. In gout, even though this affection is often seen in the vicinity of an acutely inflamed joint—the seat of a gouty arthritis—it may likewise manifest itself in a free interval of the disease. The deposition of urates demonstrated in the sheaths of the veins is no evidence, as Welch (1) observes, that gouty phlebitis is brought about in this manner. As a rule the recurrent phlebitis seen in this disease is not accompanied by venous obturation.

Quite another type of migrating phlebitis is to be found in syphilis. Instances of this have been re-

*From the medical and pathological department, Mount Sinai Hospital.

corded by Neisser (2), von Proksch (3), Mendel (4), and others. Neisser describes a case of a laborer, who was first seen in November, 1902, with a fusiform swelling of the anterior surface of the right arm, painful on pressure and especially on movement, unaccompanied by enlargement of the axillary glands, or involvement of the lymphatics. There was no redness or edema of the superficial skin. A similar mass occurred on the opposite arm. Excision of the tumor showed a good deal of granulation tissue, in the midst of which the adventitia of the vein was seen with difficulty. The intima was found to be normal. No thrombi or fibrinous deposit could be observed. The microscopic examination showed swelling of the outer and middle coats of the vessel. A localized cellular infiltration starting about the vasa vasorum composed of plasma cells and lymphocytes, as well as newly formed bloodvessels, were some of the striking features. Mercurial treatment caused prompt disappearance of the lesions.

NONSYPHILITIC TYPES

Under the title of Phlegitis Migrans Nonsyphilitica, Gottfried Schwartz (5) discusses several cases of advanced pulmonary tuberculosis in which, under observation, fusiform swellings developed on the forearms which were regarded as phlebitic in nature. At autopsy the intima of the involved vein, as well as the muscularis, was normal. The elastica was stretched in several places, the media thickened throughout to almost two to three times its normal size by the proliferation of connective tissues, with considerable new formation of bloodvessels and cellular infiltration. In spite of evident inflammatory changes no microorganisms were found. In contrast to syphilitic phlebitis, therefore, the cell infiltration was much more profuse. In the luetic form, collections of cells were more closely grouped about the smaller vessels and interspersed between areas of relatively normal tissue.

RECURRENT PHLEBITIS

Quite in contrast to the types mentioned above that have to a certain extent been coexistent with disease entities which may perhaps be regarded as etiological factors, there is a group of cases apparently constituting a disease *sui generis,* which Briggs (6), describes under the title of Recurrent Phlebitis of Obscure Origin. These cases present a type of vein involvement that bears a strong resemblance to the types of recurrent phlebitis observed in gout or rheumatic fever.

In all, Briggs presents seven cases, remarkable as he states "for their spontaneity as well as identity of clinical detail." He concludes his observation with the statement that in going through the literature he finds numerous articles professing to deal with spontaneous phlebitis, analysis of which, however, proves that they are associated with anemia, cachexia, typhoid fever or other infections, as well as cases where there are other recognized factors in the production of thrombosis. He quotes Daguillon (7), who had described five cases presumably resembling such as he presented, as of the opinion that these had occurred in socalled nongouty arthritis and labeling them as due to the influence of a lithemic diathesis. In the twelve cases reported by Daguillon, three patients died of embolism, and six were afflicted with embolic phenomena of varying severity. Daguillon's conclusions are, that there is "a primitive form of phlebitis, i. e., one without any immediate determining cause," and that such phlebitis is an indication of a general diathetic influence, shown in an arthritic constitution, with or without actual gout.

Briggs is disinclined to accept the applicability of Daguillon's observations to his own cases, and submits the opinion that these were based on a phlebosclerotic condition, rather slight to be sure, but present in all the vessels which he has been able to examine. He emphasizes that sclerosis of the veins may progress intermittently, at times with great rapidity. He disagrees with Daguillon as to the gravity in the progress, and considers that the majority of instances which occur are usually so mild that they are not reported. It would seem from this that Daguillon makes no distinction between phlebitis as such and phlebitis with thrombosis. Although superficially, as has been mentioned, the clinical appearance of both is the same, the essential point is that simple migrating phlebitis does not lead to embolism and its consequences.

SIMPLE MIGRATING PHLEBITIS

More recently records of simple migrating phlebitis have been reported by Phillips (8), in a young acromegalic, with a fatal issue, and by W. W. Herrick (9), in an old lady of sixty in whom the migrating process was manifested in the lower extremities as well as in the superficial epigastric veins. The latter finally disappeared without any residual thrombosis, thickening, edema, or pigmentation.

In this connection, it is of interest to note a case which Connor (10), reports, that of a man who had an idiosyncrasy to fish and shellfish, the consumption of which was immediately followed by redness, tenderness and swellings along some part of the course of the internal saphenous vein of one or both legs. Here apparently was a case of sensitiveness to a foreign protein, with resultant disturbances. Thus we see that in the course of a number of clinical conditions, spontaneous affections of the veins may arise, for which we have little explanation, and which may lead ultimately to a variety of complications more or less serious. In the course of the last few years a number of cases have come under my observation, two of which present a pathological involvement of the veins of sufficiently unusual clinical interest to become the subject of this report.

CASE HISTORIES

Case I.—I. O., a male nurse, presented himself in November, 1920, complaining of pains in the calves of both legs, along the inner surface of both thighs, and in the right popliteal space. These pains came about rather suddenly the day before admission to the hospital while he was up and about working. At the age of thirteen he had had "rheumatism" with involvement of all the joints. This was complicated by valvular disease which, however, had not given him much trouble. In 1910, while in Africa, he had another socalled rheumatic attack with joint involvement, which gradually subsided. He thought that he was again afflicted with rheumatic

fever. He stated that at the onset his legs were swollen and painful, especially on motion. The general swelling disappeared, but erythematous nodules on the calves of both legs and several spots on the adductor surface of the left thigh, painful to the touch, remained. He presented no other symptoms except some cardiac palpitation.

Physical examination revealed a rather poorly nourished individual with slight exophthalmos, and marked arterial pulsation in the vessels of the neck. His heart was much enlarged, fifteen centimetres to the left and seven to the right. At the apex was heard a systolic murmur which was also perceptible at the base and transmitted to the vessels of the neck. A diastolic murmur was likewise heard in the third left interspace. The lungs were negative. The spleen was enlarged two centimetres below the costal margin.

The upper extremities were entirely negative, while the lower manifested patches of erythema two to three centimetres in length, 1.5 centimetres in diameter, elliptical in outline, following the course of the superficial veins on the inner side of both calves to about the midline posteriorly. There were three nodules along the inside of the right thigh, two on the left along the adductor area, and several on the external aspect of the left thigh a few inches below the gluteal fold. These were raised, very red centrally, gradually shading off into healthy skin, and sensitive to both touch and pressure. Accompanying this was a temperature of 100°. The veins below the affected area were cordlike. The blood pressure was systolic 125, diastolic 40. Wassermann reaction was negative, the blood count normal. Repeated blood cultures were also negative.

Under observation the nodules gradually disappeared. The tumefaction became less marked and the erythema disappeared. Two months later, nothing but somewhat cordlike thickenings remained. At no time was there any edema or swelling of the extremeties. Four months later practically no evidence of the involvement remained and the patient was up and about at his work. Excision of one of the nodules in the subsiding stage was performed. The microscopic sections showed evidences of periphlebitis. The fat around the vessel was invaded by round cells and fibroblasts. In one area the endothelium of the intima showed slight proliferation. No thrombosis or endophlebitis was present.

THROMBOPHLEBITIS MIGRANS

In contrast to this case is the following:

Case II.—S. G., thirty two years old, a canvasser by occupation, was admitted to the Mount Sinai Hospital on August 7, 1920, complaining of swelling of the legs for the past ten months and enlargement of the abdomen for three weeks. He suffered from what he called indigestion for eight years at varying intervals. He would get epigastric distress one or two hours after eating with acid and gaseous eructation. This was diagnosed as nervous dyspepsia.

On admission to the hospital he stated that ten months ago he began to have severe pain in the back of his right knee, which subsequently swelled. One week later the other leg swelled and on standing up the veins of his extremities became distended. On lying down the swelling subsided. Three months after the onset he experienced severe pains on the inner aspect of the left thigh, which also became swollen. Three weeks before admission he noticed a gradual enlargement of the abdomen and with it the epigastric pain and distress had become constant, radiating to the left chest and shoulder, and aggravated by the taking of food. He was habitually constipated, his appetite was poor and he had lost ten pounds in weight in three months. He had no symptoms referable to the cardiorespiratory or genitourinary tract.

Fig.—Patient in Case II.

Physical examination showed a poorly nourished male adult of about thirty-three, chronically ill. The right pupil was slightly larger than the left, but both reacted to light and accommodation readily. There was nothing abnormal in his nasopharynx, or mouth. Examination of the chest revealed dullness at both bases, especially on the right, which extended high up into the axilla. Here were noted distant bronchial breathing, and absent fremitus. The heart was normal. The peripheral arteries showed no thickening. The pulse was regular; and the blood pressure showed a systolic of 90 and a diastolic of 60. The abdomen was markedly distended—eighty-three centimetres in circumference at the umbilicus—shifting dullness and fluid wave being present. The upper border of the liver was at the fifth rib, the lower about four centimeters below the costal margin. It felt firm, had a somewhat irregular edge, but a smooth surface. The spleen and kidneys were not palpable. Rectal examination was negative. The patient's upper extremities showed nothing abnormal; in the lower edema of both legs. Examination of the blood showed white blood cells 8,400, polymorphonuclears sixty per cent., eosinophiles two per cent., basophiles one per cent., lymph thirty-six per cent., myelocyte basophiles one per cent. Subsequent blood counts showed no abnormalities.

Paracentesis abdominis was performed and three thousand c.c. of straw colored fluid was withdrawn of low specific gravity, the bacteriology of which was negative. Three days later the right chest was tapped and 900 c.c. of straw colored fluid was removed which was also negative. Gradually the veins over the chest became prominent. The enlargement began over the third interspace near the sternum, branching downward, joining the caput medusæ formed about the umbilicus. On September 10, 1920, there developed small ulcerations on the buccal mucosa one to two mm. in diameter which were very painful. About the same time small fusiform swellings three centimetres in diameter, hot and tender to the touch, which were diagnosed as localized areas of phlebitis, appeared on the inner side of the right thigh and lower part of the left leg. Thereafter, new nodules occurred from day to day scattered over both lower extremities and lower abdomen. Simultaneously with the development of new nodules, the temperature rose to 101° accom-

panied by a chill. On three occasions with pain over the hepatic area and distinct enlargement of the liver, the temperature rose to 103° and the chill was unusually marked. This was interpreted as being due to thrombosis of the hepatic veins. Blood cultures, both aerobic and anaerobic, taken simultaneously with the rise in fever, were repeatedly negative.

Gradually the symptoms subsided. Ascites disappeared. The dulness at the right base remained, but the breath sounds were distantly audible. The patient began to get better, he gained about ten pounds in weight and his liver receded from eleven to six centimetres. Laboratory investigations showed that the Wassermann reaction was negative, the blood chemistry normal, and the gastrointestinal x ray, as well as analysis of his gastric contents, were negative. Throughout, there was no evidence of jaundice. The patient was discharged with the diagnosis of migrating thrombophlebitis, with partial thrombosis of the hepatic veins.

Six months later he was readmitted to the hospital. Since his discharge he noticed a recurrence from time to time of new nodules, confined to the peripheral veins, especially over the abdomen. There was, however, no return of his ascites. This time he complained of marked pain in his left thigh, which was considerably swollen and edematous. There was obviously a deep thrombosis of the femoral vein on that side, with the surface veins considerably dilated. The superficial thromboses of the abdominal veins were especially marked, resembling nodules of erythema nodosum. Herpes of the mucous membrane of the mouth and small ulcerations on the scrotum, possibly due to venous thrombosis, were particularly annoying.

With the idea of the condition being a low grade bacterial infection, skin tests were done with various bacteria to see whether the patient reacted to any of the proteins of these. Mild reactions, mostly erythema, were obtained to Staphylococcus albus, Micrococcus tetragenus, Streptococcus viridans, and Bacillus coli. Vaccines are made of these organisms and a course of treatment instituted. The relief obtained as a result of the vaccines was transitory. For a number of weeks no new nodules appeared. In view, however, of previous spontaneous remissions, the freedom from symptoms during the administrations of vaccines was not stressed.

For the two months following the patient was under observation in the clinic, and during that time he had another attack of pain in the hepatic area associated with difficulty in breathing, enlargement of the liver, but no ascites. This soon subsided and the patient improved. The improvement, however, was transitory. He returned in February, 1922, with an enlarged abdomen, which obviously contained fluid, and several new nodules in the right lumbar region. He was again sent back to the hospital, where a paracentesis abdominis was performed. Thereafter, numerous new nodules of phlebitic origin recurred, scattered over the superficial abdominal veins. The ascites again supervened. He was tapped on March 17, 1922, only to have the fluid come back, necessitating its withdrawal on the 25th. On April 11th another paracentesis yielded about three quarts of bloody fluid, probably as a result of the rupture of the internal varices. In May he was considerably worse. The fluid had reaccumulated and on May 8th seven quarts, amber in color, were withdrawn. On the 22nd he passed four ounces of fresh blood by rectum. On the 28th he was tapped again. On June 6th three quarts were removed and on the 11th eight quarts. On the 19th paracentesis in the midline yielded some greenish material which on microscopic examination had the structure of cellulose. On going into the right flank a quart of fluid was obtained, indicating that it had become sacculated. Repeated cultures and smears of this fluid were negative. Following this last paracentesis, peritonitis developed and the patient died.

PATHOLOGY.

Although no postmortem examination was permitted, a nodule removed during the life of the patient presented a very striking picture. The vein showed a marked perivascular infiltration, characterized by numerous mononuclear and polynuclear cells. This exudate was most marked about the adventitia, although the media as well as the intima were involved. In one area of the intima marked proliferation of the endothelium was observed. Filling the lumen of the vein this outpouring of mononuclear and polynuclear cells was so dense as completely to occlude it, and in various places there was evidence of attempt at organizations of the exudate with fibroblasts.

The picture outlined above strongly recalled the early or acute stages of the specific lesion seen in the migrating phlebitis described by Buerger (11), which may occur months or years before the true condition, thromboangiitis obliterans, becomes manifest. Clinically, it may so dominate the situation that one loses sight of the underlying disease of thromboangiitis obliterans. Should the veins be examined microscopically in the early acute stages of the superficial phlebitic nodule, the picture according to Buerger is most characteristic. "The media, adventitia and perivascular tissues are infiltrated with polynuclear leucocytes and the lumen of the vessel is completely filled with red clots. In the peripheral portions of the clot, larger or smaller foci of leucocytes (purulent foci) begin to form, whose growth occurs by virtue of migration of leucocytes. Then certain peculiar giant cell foci develop and are characteristic. They contain giant cells, endothelioid cells or angioblasts and numerous broken down leucocytes. These foci then undergo connective tissue replacement. The giant cells gradually disappear; numerous small vessels are formed, the final product being a fibrous nodule containing vessels and some pigment." With this stage, of course, the healed or organized lesion supervenes. When that occurs in the artery as well, the development of fibrotic tissue in the adventitia binds together artery, vein and nerves.

Our case presents a certain similarity to the early stage of the phlebitis occurring in this condition, in the tremendous perivascular invasion, as well as in the exudative involvement of all the coats of the vein. One might venture to designate it as a prototype of the acute, or specific lesions of the phlebitis described by Buerger. In both, the etiology is obscure, but here the resemblance ends. In our case, no arterial disease was found. There were no giant

cell foci. In the veins, no angioblasts, no tendency to the formation of small vessels, none of the more or less characteristic fibrosis of the thromboangiitis obliterans prevailed. What is most important clinically, thromboangiitis obliterans, as far as is known today, is a disease of the vessels of the extremities, arteries and veins, and there are no cases recorded, where hepatic veins have been involved by this process.

DISCUSSION.

In searching the literature for analogous instances, one is struck by the fact that although descriptions of closure of the hepatic veins had been recorded, few present such a striking clinical picture of events as in Case II. Diagnosis of thrombosis of hepatic veins is not easy, especially when there are no peripheral thromboses to give a clue to the pathological processes going on within the abdomen.

Primary occlusions of the hepatic veins have been described by a number of observers: Budd (12) in 1846 was one of the first, Frerichs (13) in 1861, Eppinger (14) in 1876, Schuppel (15), in 1880. Chiari (16) in 1899 under the title of Obliterating Phlebitis of the large trunks of the hepatic veins as a cause of death described three cases. Umbrieit (17) in 1906 reported a case in which he found a chronic thrombotic process in the radicles of the large hepatic veins which gradually extended into the larger branches of the hepatic veins although he discerned no phlebitis.

Hess (18) in 1905 collected a total of twenty-five cases out of the literature in which the associated thrombosis of the hepatic veins was thought to be due to perihepatitis in five, hepatitis in three, thrombosis in one, trauma in nine, and congenital influences in one. He stressed the importance of opening the hepatic portions of the inferior vena cava and the hepatic veins and examining for thrombosis and obliteration. His own case was that of a girl of sixteen who was first admitted to the hospital at Prague at the age of twelve and discharged with a diagnosis of cirrhosis of the liver because of her ascites from which she recovered. She returned four years later, extremely cyanosed with a recurrent ascites, and markedly dilated veins over the abdomen which contained tender nodules (probably areas of thrombophlebitis). Both liver and spleen were enlarged. Death followed quickly. At postmortem, obliterations of the hepatic veins at the ostia in the inferior vena cava were found and obstruction of the hepatic veins in the liver. Acites and thrombosis of the mesenteric veins with hemorrhagic infiltrations of part of the small intestines were also present.

Hess concludes by saying that this was a case of very long standing. For years before, in all probability the patient had had an endophlebitis of the hepatic veins. Later she improved, due to compensatory circulation which, as the autopsy showed, had established itself. The endophlebitis continued, causing stenosis of the ostia to become more and more marked until ultimately complete obliteration occurred. This final obstruction preventing the outflow of the venous blood from the liver, marked the end of the patient, leading to the sudden and persistent ascites with exitus.

Since Hess's paper numerous other cases have been recorded. Very recently Hoover (19) has published two cases with similar histories and clinical pictures and Nishikawa's monograph contains a detailed description of the twenty-nine cases on record plus seventeen personally observed by him. All of them sooner or later presented clinical symptoms similar to portal obstruction, overshadowed finally by hepatic insufficiency.

Theodore Thompson and Hubert M. Turnbull (21) classify cases of hepatic vein obliteration into two clinical groups; one group with rapidly supervening ascites consisting of a transudate of low specific gravity, 1.004 to 1.014, acute enlargement of the liver, absence of jaundice or bile in the urine, and in the end evidencing extreme cyanosis though no cardiac dilatation is obvious; a second with a more gradual onset, with similar symptoms, the patients presenting themselves at a stage when the disturbance of the portal circulation with extreme symptoms appear.

Our case probably falls in the second group in which the course is progressively slow, and, similarly to Hess's case, the ascites subsides and the patient goes on comparatively well until the final act of decompensation.

SUMMARY AND CONCLUSIONS.

After comparing the variety of clinical and pathological data presented both by our cases and those of others, we note definite contrasts. We see instances of a disease process of the veins which in one stage shows itself as a mild migrating phlebitis without thrombosis ending in complete recovery. Others where thrombosis supervenes, affecting deep as well as superficial veins, leading occasionally to embolic phenomena of the heart, lungs, etc., and finally, cases where involvement of veins of larger calibre like the vena cava or the hepatic veins, takes place with progressive thrombosis which at the last usually leads to hepatic insufficiency and death. The diagnosis of thrombophlebitis of the hepatic veins is comparatively easy when the lesion manifests itself in the extremities first in a migrating form, provided all other of the above mentioned signs are present. That, however, is not always so. Closure of the hepatic veins may and often does take place independently of any outward manifestations of this disease, and altogether apart from a generalized migrating thrombophlebitis.

Nonsurgical Biliary Drainage*

M. GOLOB, M.D.,
New York

The origin of the Meltzer-Lyon method of biliary drainage is traced to a statement which modestly appeared as a footnote in a publication by the late Dr. Meltzer in April, 1917. This footnote fell under the observation of Dr. Lyon, of Philadelphia, who developed therefrom a simple, precise, and highly scientific technic which holds much of promise in the diagnosis and therapy of biliary disease. That divers maladies should spring from biliary disorders is, of course, due to the fact that the bile itself has various functions to perform. The development, therefore, of a dependable method which gives physical access to the bile and thus permits unhampered study of its chemistry, was desirable.

Though bile is primarily an excrementitious substance and serves as such, it differs from the other excrementitious substances in the body economy, in that, through its ability to energize the activity of the pancreatic enzymes, it possesses a well defined power for promoting intestinal digestion. It also emulsifies, and by reason of its alkalies saponifies the fats, thereby aiding in their osmosis as they traverse the alkaline impregnated intestinal mucosa. It is to this virtue of hastening absorption that its antiseptic powers must be attributed. Or else, as Ott (1) tersely questioned, how can the bile prevent putrescence of intestinal contents, when it, itself, easily becomes putrid on standing?

Another function of bile of great importance to digestion is its help in destroying the pepsin, the activity of which, when unrestrained, weakens the proteolytic action of trypsin and erepsin. Bile has also a purgative action arising from its property of increasing the peristalsis and secretion of the intestinal mucosa. Is it at all surprising, in view of its multifarious activities, that the absence of bile from the intestinal tract should give rise to many ills?

Secretion of bile is continuous, though poured intermittently into the intestines in a quantity computed at approximately one thousand c. c., and varying directly with the number of meals a day—a condition of which advantage is taken in the treatment of biliary stasis. "A fasting stomach will not cause ejection of bile," says Bruns, from which it is evident why frequent though small feedings are given a patient in such conditions as achylia gastrica associated with cholecystitis, or where the surgeon desires to occlude a biliary fistula (2).

Because of its purgative action when injected into the intestinal tract, magnesium sulphate plays an important rôle in the Meltzer-Lyon method of biliary drainage. According to Hare (3) this action follows as a result of these three properties of the salt, that is, it depletes the intestinal bloodvessels, it stimulates peristalsis, and when dissolved, it is not readily absorbed. Indeed, the demonstration by Meltzer of the valuable purgative properties of magnesium sulphate has led to its widespread application as a therapeutic device. Soper (4) applied a twenty-five per cent. solution of the salt directly to hypertonic or contracted segments of the intestines, and proved conclusively that magnesium sulphate was capable of relaxing such contractures, thus providing a new and effective treatment of obstinate constipation. It is pointed out by Hare that Meltzer and others have shown that the intraspinal injection of magnesium sulphate into the subarachnoid space aids materially in controlling spasms of tetanus and often induces sleep. If the injection of this salt may have an effect sufficiently powerful to induce a state of complete inhibition, it is not at all surprising that, when applied locally, it should produce a relaxation of the sphincteric action of Oddi's muscle. This, in turn, according to Meltzer's theory of crossed innervation, is followed by constriction of the gallbladder and consequent ejection of the bile.

The technical procedure of effecting a biliary drainage is as follows:

1. The patient is to be studied after a twelve hour fast. The mouth is rendered approximately aseptic and the tube is sterile when passed.

2. The patient is placed in a right modified Sims's position with thighs well flexed on the abdomen—a posture to be maintained during the entire procedure. As much as may be secured of physical comfort, pleasant environment, and freedom from embarrassment is desirable, so as to overcome any inhibitory influences arising from psychic upsets.

3. The bucket of the tube passes through the pylorus and into the duodenum. According to Smithies the rate of deliverance by the pylorus does not vary with the individual habitus, this being contrary to the opinion commonly held for some time, that passage is more rapid in sthenic than in asthenic types. That passage has been effected may be ascertained as follows:

a. Aspirate and test with congo solution. If the tube is out of the stomach the solution is congo negative. Where it is known that a state of achlorhydria exists, test with blue litmus to ascertain the reaction; if acid, the bucket did not pass through the pylorus.

b. Introduce by syringe about half an ounce of water followed by several syringefuls of air so as to expel the water from the tube. Aspirate immediately. If the recovery of water injected is less than one third, the tube has entered the duodenum.

c. In some cases, borborygmus follows the injection of air. This is evidence of successful passage.

d. It is maintained by Jutte that where passage has not been effected, the administration of a little drinking water to which some bicarbonate of soda has been added, aids in relaxing the pylorus and facilitates the onward passage of the tube.

e. Fluoroscopic examination is *par excellence.*

4. Where a condition of vagotonia or a reflex state of pylorospasm prevails, making passage through the pylorus difficult, recourse is had to the administration of some antispasmodic such as atropine sulphate, or to a several days' use of bromides, belladonna or benzyl benzoate in appropriate doses.

5. After the bucket has entered the duodenum,

*Read before the New York Physicians' Association, May 23, 1923.

thirty c. c. of a twenty-five per cent. magnesium sulphate solution is injected slowly and permitted to remain for three minutes, whereupon aspiration is begun. By this procedure at least one half of the solution is recovered, thereby avoiding intestinal stimulation.

6. Drainage with magnesium sulphate solution is made from four to six times at each sitting, which should take place at six day intervals.

7. Both microscopic and cultural examination of the drained bile should be made immediately after aspiration. Prompt action is necessary in order to avoid digestion of epithelial pus cells and white blood cells, made possible by the admixture of the pancreatic juice and bile in the duodenum. Immediate examination will also obviate the problems arising from the possibility of symbiosis of nonpathogenic and pathogenic microorganisms. The former multiply with so much greater rapidity than their feebly reproducing associates, that delay in examination may permit the extinction or obscuration of the pathogenic bacteria, and thus an important point in the diagnosis may be lost. That microorganisms constitute a prolific cause of gallbladder pathology is indicated by the following observations made by Smithies: Of a given number of patients, viable colon bacilli were returned by 75.4 per cent.; staphylococci, by 14.9 per cent.; streptococci, by 5.26 per cent.; and yeast bacillus, typhosus, micrococci and indefinite organisms were found in 4.38 per cent.

8. Where drainage of the gallbladder cannot be effected, and the failure cannot be traced to a fault or break in the technic, the inference may be drawn that the flow is blocked by a cystic duct that is either partially or completely obstructed. In this instance, biliary drainage is not only, to a degree, diagnostic, but from the viewpoint of etiological therapy, is contraindicated.

9. Not all patients are suited for treatment by biliary drainage. This point is stressed by Smithies, Karshner and Oleson (5), who cite the possibility of a "physiological block" in the excreting apparatus —a phenomenon exhibited when the normal neuromuscular reflex fails to function. They mention, as obstructive of bile drainage, such factors as organic cord lesions, fatigue, apprehension of the procedure, or any disturbance which may arise in the course of the hepatic biliary system, conducive to a disruption of the reflex arc. Application of the Meltzer-Lyon method to a patient unsuited for the treatment, has often mistakenly led to its condemnation.

In concluding the description of the technic, it may be of interest to compare the method with that suggested by Kiralyfi (6) for the study of bile in cholecystitis. This method consists of gastric lavage of sterile water followed by the introduction, through a sterile tube, of a breakfast of 250 to 300 c. c. of sterile olive oil, which is removed after an hour and a half. The oil and bile tinged fluid, which by this time have entered the stomach, are separated—the oil, of course, rising to the top. This comparatively complicated procedure was intended to aid in the diagnosis of socalled obscure cases—particularly in suspected cases of chronic typhoid infections of the gallbladder. The simplicity of the mechanism of the Meltzer-Lyon method is emphasized by the comparison. Moreover, if we but recall some of the indications for which a cholecystotomy is practised, and for which the nonsurgical biliary drainage can be substituted, the serviceability of the Meltzer-Lyon method cannot, in truth, be disputed.

The pathogenesis of the gallbladder being in the main bacterial, our efforts must of necessity be initiated at such a phase of the malady as to render our work, in the main, of a preventive nature. That is to say, a mere symptomatology suggestive of a disturbance of the hepatic biliary system calls for treatment. Thus it is desirable that biliary drainage be resorted to at a stage of prepathology, and, most important, of precalculus formation.

It is pertinent here to recall the factors of calculi formation, viz., a suitable soil, a nucleus, formation of inflammatory débris, and solid constituents of the current fluid. The renal calculus is built of a nucleus, deposition or precipitation of solid constituents of the urine, whether normal or abnormal, layer upon layer, until it assumes the proportions of a stone. In pancreatic calculi the chemical constituents are carbonate and phosphate of calcium. Their origin, as pointed out by Elsner (7), is due to stasis and infection. The biliary calculus has a similar origin, being brought about by a phase of catarrhal cholecystitis, most probably bacterial in causation, and by epithelial desquamation, albuminous exudation, and increased formation of mucus and cholesterin. The Eberth bacillus has been known to furnish the nucleus. According to Musser (8), it is probable that the bacilli are agglutinated by the bile, thus establishing a nucleus for the formation of a calculus. It is at the conditions conducive to this nuclear formation that biliary drainage is largely aimed.

In his plea for a more painstaking diagnosis of chronic cholecystitis, Willy Meyer (9) draws attention to the number of authors who doubt the conclusiveness of the cholesterol test of the blood as a diagnostic agent in cholecystitis with stones, let alone cholecystitis without stones. He is quite emphatic in his belief that the analysis of the duodenal contents is an achievement that ranks as one of the greatest advances clinical medicine has made in the last half decade. He does not favor the use of the Meltzer-Lyon method for diagnostic purposes, yet holds that in the treatment of diseases of the biliary system the method will grow in importance.

The criticism directed at the method by Bassler, Lucket and Lutz (10) must, upon analysis, be dismissed because of the conditions under which their investigation was conducted. It is well to bear in mind that the Meltzer-Lyon method was built up primarily by dynamic study, from the observation of patients who retained full consciousness under treatment. Yet the cases selected by these writers, from a study of which they draw their conclusion of disapproval, were in every instance passive in nature—that is, with the patient under the influence of anesthesia. In this condition, muscular relaxation is a natural sequence. As an example, in deep narcosis an hour glass constriction of the stomach disappears. Similarly, in the cases cited by these writers, there was a break in the arc of the neuromuscular reflex, which disturbed the interrelation between the contracting gallbladder and the inhibitory action of Oddi's muscle. Thus, observations were made under

conditions where the "law of contrary innervation" —the very foundation of the method as laid down by Meltzer and built upon so ably by Lyon—was, for the time being, suspended. "The gallbladder," says the report, "was gently held in the hand of the operator for eight minutes. It did not contract nor diminish in size." Is it at all surprising that a muscular structure under the influence of a general anesthetic should fail to contract? The effect of this experiment, if any, is to fortify my belief that the Meltzer-Lyon method contains potentialities of great diagnostic and therapeutic value. Time and experience will bring them to fruition.

To my mind, Dr. Lyon is correct in his statement that the gallbladder is like the urinary bladder in function. The latter acts similarly as a reservoir out of which the urine is expelled by contraction of the detrusor muscle and corresponding relaxation of the sphincter. The only difference is that while the action of the urinary bladder is voluntary, that of the gallbladder is involuntary. The latter is thus under influence of the cerebrospinal system, which, in a condition of general anesthesia, simply inhibits, for the time being, the vital functions of the parts controlled by it. In this condition, inhibition of the gallbladder, not its contraction, should be the expected manifestation. It is hardly worth stating that nonsurgical biliary drainage is not intended as a substitute for surgical intervention in well verified diagnosis of gallbladder disease. I advocate mainly its inclusion in the routine of examinations along with urine and blood analyses and serological studies.

From the viewpoint of preventive medicine, according to Lyon (11) and his coworkers, the group of cases in the routine examination of which biliary drainage is particularly to be included, are those with a history of typhoid, influenza, recurrent attacks of tonsillitis, catarrhal jaundice, biliary migraine, severe headaches, and those cases "which have a progressive brownish pigmentation of the skin and which frequently show some jaundice of sclera and of the hard palate and cases of visceroptosis with biliary stasis from partial obstruction occasioned by traction on the supporting peritoneal attachments in the right hypochondrium."

Drainage is particularly effective in overcoming biliary stasis. Hence it is indicated in posttyphoid cases and in cases of gastric anacidity or subacidity where the bile tends to become static because the stimulus furnished by the normal flow of gastric juice is wanting. It is also effective in states of emotional jaundice (Meltzer) wherein the physiological storage of bile is converted into pathological stagnation.

Dr. Willy Meyer (13) points out a technical advantage that may be secured from a preoperative biliary study when the question of appendicular pathology arises. Such a study may aid the surgeon in making his decision "where to incise and what to excise." For, if preoperatively the surgeon be cognizant of pathological bile, he will cut down on the gallbladder region and pull the cecum and appendix up, in lieu of making an incision over McBurney's point and then investigate the gallbladder region.

Perhaps it is worth noting that where the presenting symptoms may indicate a choice of diagnosis as between biliary dysfunction and some other condition, there is a widespread tendency among practitioners to assume the former. And they regard efficacious treatment as confirmatory of the diagnosis. However, it is well to bear in mind that an apparent *propter hoc* may in such an instance be only a *post hoc,* and that further search would have revealed a different offender. In such cases biliary drainage would establish, at least, a negative diagnosis.

Dr. Kellogg asserts that he has derived valuable information from a study of the bile aspirated through the duodenal tube. He found it striking to compare the clear golden bile of the biliary tract with the turbid green or dark brownlike fluid containing flocculent mucus observed in pathological stasis. And this difference was often the point that sealed the diagnosis.

Hopkins (14), of Philadelphia, has shown that the duration of jaundice in a group treated by the new (Meltzer-Lyon) method averaged twelve days, as against an average of seventeen days in a group treated by the old method; that an average of only six and a half days of drainage was required to clear the jaundice, and that after the first or second day of drainage the patient underwent a symptomatic recovery. I believe, emphatically, that "the duration of catarrhal jaundice may be considerably shortened by the new and direct method of treatment; that if this method of treatment be applied at the first appearance of the jaundice, one may naturally expect a shorter duration than by any other method."

Speaking from my own experience in both the Vanderbilt and the Bronx Clinics, I have found that patients presenting a symptomatology of biliary stasis responded satisfactorily, on the whole, to a treatment which consisted of four to six successive biliary drainages at six day intervals. Some cases showed a complete arrest of symptoms, while at least a partial arrest was evidenced by the others. And, most important of all, in all my cases a cytological study of the bile obtained in the last drainage operation revealed none of the pathological elements found in the early drainages.

My experience with cases of frank icterus is substantially in line with that of Hopkins, given above. Response was especially prompt in cases of jaundice following salvarsan injection, i. e., arsenical poisoning. It is now my conviction that the old method of drug therapy should be discarded, whenever possible, for the Meltzer-Lyon method.

In conclusion, I wish to reiterate my belief that biliary drainage will grow in importance with use. I believe that its merits have been sufficiently established to warrant its inclusion in the routine of medical examination on a par with urine and blood analysis and serological study. When it is considered that as a diagnostic agent it may, on the one hand, lead to negative findings and thereby prevent unnecessary surgery; and on the other hand, by revealing static biliary conditions, warn us in time to prevent gallbladder pathology with all its sequelæ; when also it is considered that the very process, *per se,* sets static bile in motion and is thus a curative, its place in medical practice must become an accepted fact.

A Recommended Procedure for the Relief of Ala Deformity in Certain Cases in the Adult Associated with Hare Lip and Its Mechanical Counterpart*

J. EASTMAN SHEEHAN, M.D., F.A.C.S., M.R.S.M. (London),
New York,
Associate Surgeon and Lecturer to International Clinic for Otorhinolaryngology Maxillofacial Surgery, Paris; Assistant Professor of Laryngology, New York Post-Graduate Medical School and Hospital.

This procedure is recommended for your consideration and is intended for relief of deformity of the ala nares in certain cases in the adult in which there is present a hare lip. It applies to those cases having an abnormally broad nostril, with marked flattening of the ala where relief could not be wholly accomplished and a pleasing result obtained by performing one or other of the many plastic procedures recommended for this condition. The reason for this is obvious.

This deformity is caused by severe adhesions in the maxillary—ala area, which strongly bind that part of the nasal organ to the superior maxillary bone. It is similar, although not as severe as is the case in the syphilitic nose. (Drawing of the maxillary—ala area showing extent of adhesions to be freed.)

No amount of undercutting will permanently relieve this condition. The fault lies with the lack of recognition that the lining is as essential as the covering. In this deformity there is replacement of mucous membrane and musculature with scar tissue, which is firmly adherent to the underlying bone. To

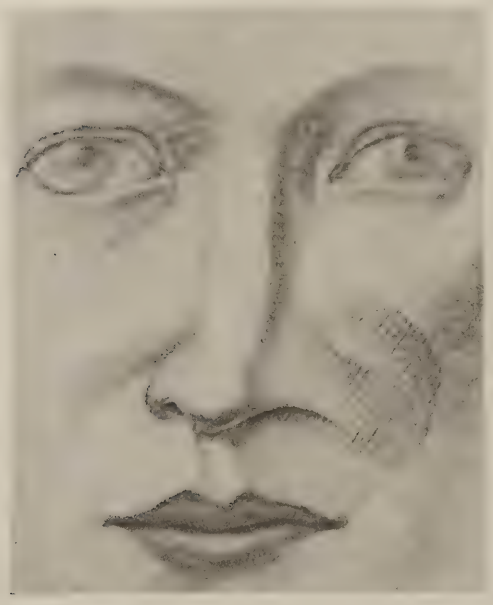

FIG. 1.—Extent of undermining alar area.

overcome this deformity it will be necessary to replace the scar tissue and disintegrated membrane by a membranous structure of a similar or corresponding function. It is obvious that mucous membrane cannot be obtained from any other part in amount sufficient to replenish that which has been removed. Consequently, we resort to the skin, the only other structure with an epithelium content, and we call this process or operation epithelization.

*Presented before the Throat Section, New York Academy of Medicine, Wednesday, March 26, 1924.

METHOD OF APPLYING EPITHELIUM

The patient is first referred to a dental surgeon who will make a small, removable cup splint to fit into the upper teeth. If the mouth be edentulous, a special plate is made to which is attached the stanchion of the nasal appliance. To the centre of the splint there is attached an upright semiflexible piece of metal with three triangular wings. The length of the splint will approximate that of the raw area.

FIG. 2.—Dental appliance which carries skin covered mould to raw area.

The drawing illustrates an actual splint made by my brother, Dr. A. Beaman Sheehan. A cupshaped splint without the upright stanchion, is fastened to the upper teeth, and an incision is made one quarter of an inch above the gingival line, extending from the nasal line backwards for some two inches. The incision is then extended upwards and laterally, separating the adhesions from the bone, which leaves a bony raw area below and scar above. It is this latter scar area which must be excised with meticulous care. This elevates the ala and lessens the deformity. To insure its permanency the raw areas are skin grafted.

A mould of Stent is sterilized by boiling. A model of the raw area is made by inserting the sterile Stent, made soft and pliable by immersion in hot water, in the alamaxillary cavity through the gum incision. The Stent is pressed upward, then laterally and then posteriorly until all the exposed raw areas are completely covered and an excess left to allow for subsequent contractions. The upright stanchion of the prosthesis appliance, heated in a spirit flame, is then inserted upwards into the mould and screwed to the dental splint. The mould, while warm, must be manipulated to insure that the proper shape of the mould area has been formed and that all the exposed raw areas are covered.

Sterile ice water is sprayed through the nostrils, causing the mould to set, and it is then removed with the stanchion unscrewed from the splint. Markings

on the mould will show where the Stent has actually come into contact with the raw areas. It is the raw area thus identified, which must be covered.

The graft should, if possible, be cut in one large piece and thin, in order that the whole mould may be covered and application to the area to be skin grafted facilitated. It is cut, preferably, from the right, inner aspect of the thigh in a nonhairy area. The graft is spread completely over the mould, raw side uppermost, care being taken to avoid wrinkles and slack.

The mould, covered with skin and attached to the upright appliance, is inserted and secured to the nose or splint attached to the teeth. It should remain *in situ* for ten days, after which it should be removed and cleansed. Inspection of the area now shows the formerly raw areas covered with an epithelial lining. A mould of gutta percha is then made, patterned after the original one of Stent, and inserted into the newly lined area to take the place of that removed. It is removed daily for cleansing purposes. Its use is continued for two months, when it is removed for good and the patient is now ready for the small plastic operation on the ala, which, in the majority of cases, gives a perfect result.

This result could not be achieved if the epithelization of the under parts had not been done, as it not only causes the ala to stay erected, but it also prevents further contractures of the ala to the maxillary bone.

Hydatid Brain Cyst

JOHN W. SHUMAN, M.D., F.A.C.P.,
Los Angeles, Cal.

That we cannot be absolutely sure of the location of a brain tumor, even when all signs point to a certain area, is an axiom in medicine. To this should be added, that we cannot be sure of the type of tumor even though all signs point to a certain type, for example, gumma, as was diagnosed in the following case. I am sure that more tumors form in the brain than is generally thought by those who hold but an occasional autopsy. The value of an autopsy is clearly demonstrated in my case, for had we not done one the clinical diagnosis of syphilitic lesion (gumma) at the base of the brain would have held as the cause of death.

Case I.—The patient, a man aged twenty-eight, had a chancre of the penis in 1918, for which he received "only a part of the prescribed Army treatment." On September 25, 1922, he consulted a physician with regard to occipital headaches of one week duration and intermittent in character. On October 2, 1922, physical findings were negative except a double plus Wassermann reaction. Antiluetic treatment was administered for the two weeks following, during which time there were no headaches, then an attack requiring morphine to control.

On October 16th, Dr. Charles Webster reported, "optic neuritis, bilateral." My consulting neurologist, Dr. Watson-Smith, found, "undoubtedly a case of brain tumor, unable to localize or to determine the character of it." Antiluetic treatment was pushed harder the next five days and there was no headache. On the 22nd the patient had a severe attack of headache and vomited for the first time. During the next seven days he was free from headache, but complained of "inability to awaken in the morning," and had trouble in "beginning the act of urination." He staggered slightly to the left.

On October 30th he had another attack which was followed by an interim of ten days' apparent improvement. He was feeling so well that he wanted to leave the hospital, and I permitted him to go. The next morning he was readmitted in a state of collapse, head drawn back, right pupil fully dilated, left pupil dilated with vertical diameter greater than transverse, breathing difficult, and masseter muscles in spasm. This picture remained the same until death at 11:30 a. m., by respiratory arrest. The autopsy findings an hour later by Dr. Douglas Cruickshank were negative throughout except for the intracranial findings, which were as follows:

Brain of normal shape; moderate congestion of meningeal vessels everywhere; a few scattered adhesions between pia and dura; hardened in ten per cent. formalin.

When the brain hardened it was noted that the right quadrate lobule where it presented in the median fissure was apparently very thin and fluctuant. A fine needle was made to penetrate this fluctuating mass from a distance and ten c. c. of clear colorless fluid was withdrawn. This was centrifuged but showed no deposit under the microscope.

A horizontal section was then made across the right cerebrum 1.5 cm. below the vertex. This opened into a smooth, sharply defined, spherical cavity six cm. in diameter. This cavity contained the clear, transparent membrane of a single hydatid cyst that had retracted because of the removal of part of its fluid and thereby remained intact. On inverting the brain the cyst rolled out of the cavity, demonstrating that it was nowhere attached to the brain substance and that the latter had not been injured except by pressure and displacement. At no place was the cortex of the brain encroached upon except in the quadrate lobule, where it was very thin.

The cavity lay within the following bounds: Anteriorly, Rolandic fissure; posteriorly, parietooccipital fissure; superiorly, superior parietal fissure; inferiorly, posterior limb of fissure of Sylvius; laterally, angular gyrus; mesially, quadrate lobe. The brain appeared large, measured eighteen cm. long by 15.5 cm. broad by ten cm. deep. It was preserved for pathological purposes and no further section was made.

Anatomical diagnosis was hydatid cyst within the medulla of the brain, encroaching upon the cortex only in the right quadrate lobule. Death was due to intracranial pressure.

Practical Therapeutics

THE VALUE OF BACTERINS IN PRACTICE

EDWARD CALVIN LAVERTY, M.D.
Louisville, Ky.

That bacterins (killed germs in salt solution) are of value as therapeutic and prophylactic agents, there is now no question. To be sure they do not in every instance of infection stay the disease and cure the sufferer. Such an ideal agent does not exist and no thoughtful physician would expect as much. Those who question the value of bacterins have had no extensive clinical experience with them, have inefficiently used them, or have not used them at all. It is interesting to note that those who questioned their value on theoretical grounds are fading out in the face of large clinical experience. Notably those who dogmatically stated that if there was any therapeutic value in bacterins they must be autogenic preparations in order to have the specific antigens.

The therapeutic results with stock bacterins and nonspecific proteins have now been so extensively proved and for such a long period that these contenders must cease to contend. It is true that some times the autogenic bacterins must be used, especially if well selected stock bacterins seem to fail.

The fundamental principle of bacterin therapy is stimulation of the natural immunizing forces of the body to produce antibodies in the healthy tissues, away from the site of infection, for the purpose of getting rid of the offending invaders (germs) and neutralizing their toxins. That this does occur has been proven by Sir Almroth E. Wright and others in extensive research work, and by the clinical results obtained by many thousands of physicians throughout the world.

In 1918 few physicians were using mixed bacterial vaccines in pneumonia. Many good men were strongly antagonistic to their use in this highly fatal disease solely on theoretical grounds. Today, mixed formulas of pneumococcus, streptococcus, micrococcus catarrhalis, Friedlander bacillus, and similar organisms are not only extensively used in the treatment of pneumonia but are fast approaching the standing of diphtheria antitoxin in what has been a highly fatal disease.

The failure to get successful results from the use of bacterins in the treatment of infectious processes, where they would be indicated, is due to a number of factors, some of them known, some probably not known at this time. We must remember that in dealing with immunizing forces there are complex phases that interfere with favorable results in some individuals, yet the proportion of good results unquestionably justifies their use in all conditions due to germ invasion and activity.

That the use of bacterins is a harmless procedure is now apparently beyond question, for their use during the past fifteen or more years and their extensive use in the past five years, have brought out no statistics to the contrary.

Bacterial vaccines must not be confused with serums or toxin filtrates that have been brought out from time to time, and occasionally cause an anaphylaxis. Anaphylaxis, however, is due to an idiosyncrasy of the patient to the serum or toxin filtrate. I have never seen or heard of an anaphylaxis following the use of bacterins. Occasionally a severe reaction will occur but today many users of bacterins consider a good reaction essential to the best results, notably in treating gonorrhea. Stimulation of the natural fighting forces in the human economy against bacterial invasion and destruction is essential.

In the light of the knowledge we now have on the subject, procedure toward activating the immunizing forces is as sensible as activating other functions and organs of the body. The time is near when failure to do this will be looked upon as an inexcusable neglect which will place the guilty physician in a position for severe criticism. The time for saying, "Let your patients alone, they will get well if you give Nature a chance by letting her alone," is over. The physician is consulted by the patient with the expectation, and justly so, that the man learned in anatomy, physics, physiology, pathology, bacteriology, therapeutics, etc., can aid Nature in overcoming the condition which the physician is asked to treat.

The physician's moral duty is to do his best and in order to do so he must keep abreast of the times and study carefully and intelligently those agencies that are brought forth from time to time that will improve his technic and obtain better results. It has been said, and no doubt it is a fact, that seventy-five per cent. of our patients would recover without the services of a physician. If this is true, our real problem is with the remaining twenty-five per cent. Let us then strive to improve materially or relieve the sufferings, and reduce the mortality of this twenty-five per cent. This is the real test of a physician's ability.

I do not believe that my contention will be denied that the majority of our real problems in medicine are due to infections. Then, the subjects of bacteriology and immunology stand out as foremost factors in our work and should receive the most earnest consideration and study on the part of the practitioner and surgeon.

The best technic in surgery counts for naught if the patient dies, so the real test of a surgeon's good work is, not so much good surgery, but satisfactory recoveries. Might it not be possible that the practice of preoperative and postoperative immunization against the well known pathogenic organisms in surgery, would reduce materially the socalled complications, that frequently either kill the patients or leave them invalids to be held up as warnings against surgery?

Several months ago my wife had appendicitis. Immediately upon the manifestation of symptoms of the disease, I gave her one half cubic centimetre of a stock bacterin. Eight hours later, just before going to the hospital, she received a full c.c. of the same bacterin. This procedure was simply to

aid Nature's fighting forces to care for the post-operative conditions. On incision the surgeon found adhesions and a bad streptococcus infection (no pus) of the appendix. It was removed and the incision closed. The condition warranted the grave attitude of the surgeon at the conclusion of the operation. To the surgeon's surprise the patient's recovery was ideal; she left the hospital in twelve days. She probably would have recovered without the use of the bacterins, but unquestionably they did no harm. The unusually good results following a careful surgical operation in this case justify the belief that the bacterins rendered valuable service.

A few weeks later a friend, with a much less serious infection, underwent a similar operation by a first class surgeon. After seven weeks of severe suffering from postpoperative infection her condition was still serious. No bacterins were used in this case.

The circumstances and results in these two cases give food for serious thought.

THE COMPARATIVELY NEW NONSPECIFIC PROTEIN

The use of a comparatively new antigen, sterilized milk, usually mentioned as milk or lactic antigen, is filtering into our armentarium of immunizing agents very rapidly. Much has been accomplished in Europe and in this country with this new stimulant to the immunizing forces, and it behooves every physician and surgeon to give it careful consideration and extensive use with critical observation to obtain its true value in medicine. It is, of course, a nonspecific protein stimulant to antibody production.

The possibility of nonspecific protein therapy was long ago recognized and established by Sir A. E. Wright and other authorities in the field of immunology. The extent of its value, however, must be proved by extensive clinical evidence. In preparing this milk antigen great care must be used in the selection of the milk which must be free from pathogenic organisms, especially tubercle bacillus. Even milk from certified dairies must be carefully sterilized. It is best prepared in laboratories equipped for the purpose.

TREATMENT OF ACUTE AND CHRONIC POLYARTHRITIS, ARTHRITIS DEFORMANS, AND SEPTICEMIAS, WITH ACTIVATED COLLOIDAL SULPHUR

W. J. Monaghan, M.D.
and Frank Garai, M.D.
Hudson County Hospital, New Jersey

(*Concluded from page* 26)

HISTORY OF TREATED CASES

Case I.—E. V., aged fifty. Admitted to hospital September 28, 1923. Severe arthritis deformans of two years' standing involving all joints, hard, cracking by movement, tophi, raising approximately one inch above joints. Practically complete immobility on admission, complaining of continuous severe pains. Wassermann negative. Focus of infection not evident.

Intravenous injections of 338 B. alternating later with 338 D, started September 29th, initial dose three c. c.; thereafter four c. c. of 338 B alternating with 338 D three times a week. October 22nd, noticeable improvement. Patient not complaining much about pains; sleeping better; better appetite. About November 15th, the patient commenced to use his hands to feed himself; could bend his knees and lift himself in bed. January, 1924, the patient was able to get out of bed with help. At present can sit in chair and stand up without pain. This case typifies most severe arthritis deformans with extensive involvement of all joints. Further, progressive improvement was noted and patient is being kept for further treatment.

Case II.—H. J., aged forty. Admitted to hospital February 13, 1924. Arthritis deformans involving knee, hip and spine joints. Ten years ago suppurative inflammation of knee joints, operated upon in the hospital; later hip joints became involved and seven years ago spinal involvement developed. Two years later was operated on his hip joints without result. General painfulness on admission. Immobility of ankles, knees, hip and spine. Walking on crutches only.

After five injections, intravenous, of 338 B alternating with 338 D, the patient could stand more easily on crutches, he had less pain and rapidly increasing mobility was noticeable. After fifteen injections patient could walk slowly without crutches, pain gone. Patient still under treatment.

Case III.—A. H., aged twenty-two. Admitted to hospital May 31, 1923. Subacute polyarthritis involving all joints. Ankle joints, spine and shoulder joints swollen and painful. Evidence of chronic tonsillitis with probability of tonsils being focus of infection.

Intravenous injections of 338 B alternating with 338 D. Clinical conditions disappeared rapidly after treatment comprising of about twelve intravenal injections. Two months after this treatment peritonsillar abscess with return of all previous clinical conditions occurred. After lancing abscess, conditions remained the same for six weeks. Patient was put back on intravenous administration of 338. After fifteen injections, patient discharged, returned home in perfectly normal and healthy condition.

Case IV.—G. E., aged forty-four. Admitted to hospital June 7, 1923. Chronic polyarthritis and pyelonephritis and Staphylococcus aureus bacteremia; ankle joints, shoulder and finger joints involved, swollen and painful. Patient walked with difficulty on crutches; trouble started two months prior to admission. Repeated blood cultures showed Staphylococcus aureus. Urine pus cells, Staphylococcus aureus, granular and hyaline casts and one and a half per cent. albumin.

Intravenous injections of 338 B, later 338 D, started June 11th. Two weeks later patient felt much better; only slight swelling of ankle joints remaining. Two months after admission to hospital, after a total of twenty-five injections, the patient was discharged in a perfectly healthy condition, and went to work. The blood culture became negative after two injections.

Case V.—N. M., aged thirty-eight. Admitted to

hospital May 9, 1923. Acute polyarthritis, acute endocarditis, tonsillitis, nephritis, past six months patient had occasional pains and swellings of various joints; two weeks prior to admission, sudden acute attack of polyarthritis with febrile manifestations. Ankle joints became swollen, immobile and the trouble spread progressively to knees, hips, shoulder and wrists. Upon admission, the patient had dyspnea. Patient complained of continuous pain day and night.

Intravenous injections of 338 B commenced May 12th. One injection given every day. There was immediate improvement. After first injection, swelling and pain commenced to recede rapidly. Patient rested and slept well. After three injections, patient sat up. On June 3rd the swelling was gone, patient walked around ward with only slight pain. Four weeks later patient appeared to be normal; heart, kidney and joint conditions having cleared out completely.

When this treatment is used the pain, swelling and inflammatory conditions recede rapidly. Bacteremias and septicemias were cleared after four to six injections, blood cultures becoming negative after one or two injections. 338 was continued, however, to prevent reinfection assuming that the focus of the infection (walled in) has not been eliminated. Chronic cases where important tissue changes had taken place showed slow but continued improvement in mobility. In all cases there is noticeable a positive stimulating effect of the preparation.

ACTION OF THE DRUG

The sulphur element of the injected preparation combines immediately with hydrogen present in the body hydrates and sets free an ionized active form of oxygen (in *status nascendi*) to react with body constituents. This occurs according to the formula $S+H_2O=H_2S+O_{(3)}$. This oxygenation process starts during or immediately after the injection and goes on simultaneously with the excretion of metamorphosed sulphur in the form of H_2S through the respiratory channels. This oxygenation and elimination process is very rapid and may end—as in the case of 338 B—within ten minutes after the injection. During the injection or immediately after, there is a noticeable odor of exhaled H_2S. It can always be detected by holding before the nostrils of the patient a moist strip of paper impregnated with solution of lead acetate. It is to be noted that electric negative charges of injected colloidal particles cause their fixation with pathogenic organism in blood which carries positive charge. This phenomenon is well known in colloidal chemistry and it is similar in effect to the action of body precipitins; spontaneous oxidation processes following this, produce positive detoxication and sterilization of the body fluids. This method of action of 338 differs from known preparations in this, that the element by itself is not toxic in the sense of arsenical, mercurial and bismuth preparations and its germicidal effects are primarily not due to the element itself but due to the oxygenation processes that it sets up in the body.

Germicidal intensity of this modus operandi is evident in this that often a single dose of seventy-five milligrams of sulphur element, approximately one tenth of a dose of well known arsenical preparations, is capable of sterilizing the blood and controlling most severe types of bacteremias with culture becoming negative within twenty minutes after the injection. The experience of the writers in this respect is substantiated by the results of the unpublished work by the late George Stuart Willis of the Post-Graduate Hospital, New York City, and William Faison. Those oxidizing properties of the preparation apart from its germicidal effect have further important value in body metabolism. This is evident in metabolic studies on blood and urine. Metabolic oxidization coefficient of blood, osmotic pressure and alkalinity are raised rapidly. Furthermore, intravenous administration of 338 influences the nitrogen metabolism profoundly. It is also interesting to note that after a few injections, acid uric in blood drops down fifty per cent. or lower; the reason for this the writers are not as yet prepared to offer. After every injection there is a marked transient leucocytosis and a steady rise in erythrocytes and hemoglobin. Studies of the influence of 338 on nitrogen metabolism will be published later.

The fact that 338 activated colloidal sulphur is an apparently positive and effective germicidal and detoxicant *in vivo* with particular affinity for pyogenic organism and that it is an oxidizer having important beneficial influences on body metabolism, that it is noncumulative and safe in administration and of great importance in general practice should not encourage the users of the drug to become unduly optimistic or careless in its administration. Its effect in each case must be watched critically and with proper application of the blood and body chemistry. Only in this way can the ultimate values of 338 and its wide adaptability in therapy and probable effects be learned and the field for its application solidly established.

The author's references will appear in his reprints.

The Similarity of Action of Parenteral Sulphur Therapy and Proteotherapy.—As a result of experimental investigations and clinical experiences, Edmund Maliwa (*Wiener Archiv für Innere Medizin,* December 1, 1923) comes to the conclusion that proteotherapy is only a part of stimulation therapy. It is not the parenterally introduced protein or its decomposition products that produces the stimulation, but rather that there is a cellular reaction in the form of a (local) stimulation of tissue. This may also result from an intravenous administration. The effects of the irritation are certainly not merely an agitation of colloids, but they bear the signs of a functional chemical influence, which is demonstrable not only by the variations in the construction of the protein of the serum, but also by the change in the hydrogen and chlorid metabolism as sensitive indicators. Proteins and inorganic stimulating bodies show not qualitative but quantitative differences in their effect; at any rate the quantitative differences can produce qualitatively different secondary reactions according to physiological and pathophysiological laws (Arndt-Schulz). From the therapeutic viewpoint, treatment with sulphur is recommended for chronic joint processes only when other proteotherapy has failed.

Historical Medicine

The History of Bathing

LLEWELLYN JONES LLEWELLYN, M. B., (Lond.),
London

Member of the Conference (Medical Research Council) on Arthritis and Allied Rheumatoid Conditions, Formerly Senior Physician Royal Mineral Water Hospital, Bath.

SULPHUR BATHS

The use of sulphur baths can be traced back to a very remote period. Thus we read in Grecian mythology that Hercules on his way through Thermopylæ encountered the Goddess Athena, who bade him lave his weary limbs in the refreshing waters of the sulphur springs that rose in that historic pass. Indeed, it has been suggested that the prophet Elijah, when urging Naaman, King of Syria, to dip himself in the waters of Jordan, was, apart from his belief in the sanctity of the holy stream, probably aware of the curative powers of a sulphur spring situated in the valley through which it coursed on its way to the Dead Sea. This speculative inference is to some extent supported by the fact that the waters of this inland sea hold bitumen, a substance, as we know, containing sulphur.

Commander Lynch also, in the course of his exploration of the Dead Sea and the watershed of the Jordan, ascertained that the hot springs of Callirhoe, which pour themselves eventually into the former, were a little sulphurous in nature. Again, the writings of Aristotle and Athenaeus attest that the fame of the sulphur springs of Eubaea in the fourth century before Christ attracted so many from all parts, that the King Antigonos imposed a polltax on those who availed themselves of their healing virtues.

Indeed, according to Plutarch, Ædepsus, the site of the most celebrated springs in Eubaea, would appear even at this remote period to have attained to the dignity of a spa, the ancient Greeks resorting thither in the springtime.

This same historian tells us that Sulla after a visit to this ancient health resort completely rid himself of the gout. The old Greek physician Ætius also in his works remarks that "the bathes of brimstone soften the sinews; they scoure and cleanse the skinne, wherefore they are good for the white morphew and for the blacke, for the leprosy."

Nor were the Greeks singular in their appreciation of the therapeutic virtues of sulphur, for Pliny's *Natural History* abounds with allusions, testifying to its good repute among the Romans. Thus, he informs us that the waters of Baiae, so beloved of Nero, contained sulphur, and adds that the cold sulphur springs of Albula promoted the healing of wounds. Although frigid, the sulphurous vapour arising from these waters was apparently so strong as to give the appearance of smoking, as is clear from a reference culled from one of Martial's epigrams, *"Canaque sulphureis Albula fumat aquis."*

Again, the cold sulphur springs of Cutilia in the Sabine territory are spoken of both by Pliny and Celsus as being suitable for disorders of the stomach. It is interesting to note, moreover, that one of these is still encircled by marble steps, and some remains of baths are still visible despite the fretting touch of time. Celsus, it appears, thought highly of the value of sulphur in nervous disorders, and Horace in one of his epistles reechoes the same belief. Agricola also, in his quaint reflections on "the things that flow out of the earth," observes "That bathes of brimstone do soften the sinews and doe heate, they are good therefore for palsie for places pulled in too much or stretched too farre forth."

Enough has been said to show the antiquity of our belief in the therapeutic value of sulphur, and the fact that we in our day enlist its aid for much the same class of ailments, as did the physicians of this bygone age, speaks well for the sagacity of these whilom followers of the healing art.

VAPOR BATHS

The special advantages of this type were fully recognized even by aborginal mankind, the North American Indians, to wit, having from time immemorial availed themselves of its refreshing and restorative effects. Thus Gent, in his *History of Virginia,* tells us that the Indians had even in the remote past devised primitive "sweating chambers" for this purpose, locating them as a rule near the banks of a river.

Upon the floor of these nearly airtight huts, a stove covered by a layer of stones, was placed, while upon these latter, when sufficiently heated, cold water was poured at intervals, thus securing the desired mixture of hot air and steam. Subsequently, the freely perspiring savage plunged into the cold waters of the neighboring stream in order to secure the necessary reaction. Similar crude contrivances were also in vogue among the ancient Mexicans, Celts and Finns and had, moreover, for many centuries been in high favor with the Chinese and Japanese peoples.

More particular information is to hand regarding the "sweating houses" or "Tig Allui" of the early Celts of Ireland, which, according to Urquhart and Haughton, were capable of accommodating six or eight persons at one time, the latter authority, however, stating that smaller varieties admitting of only one occupant were also in use.

As might be expected of so cultured a people, the Greeks were quite conversant with the vapor bath, which, indeed, they brought to a high pitch of perfection; Herodotus, when animadverting on the Scythians habit of burning hemp, observes that the smoke produced was "such as no Grecian vapor bath ever exceeded." Subsequently the Greeks designed their well known hypocaust of which, indeed all, our modern vapor baths are but replicas with accessories designed to meet the need of more luxurious days. Briefly described, the hypocaust consisted of a furnace situated beneath the "sweating chamber" whose walls were surrounded with flues connected there-

with. Public baths of this nature flourished greatly among the Greeks and were eventually imitated at Rome.

Here we must refer to a highly interesting passage in the writings of Celsus which runs as follows:

"Sudor etiam duobus modis elicitur aut sicco calore aut balnec"

"Siccus calor est et arenae calidae et laconici et clibani e et Quarundam naturalium sudationum ubi e terra profusis calidus vapor. Aedific includitur sicut super Baiae in myrtetis habemus."

The foregoing statement by this old physician seems to indicate that, at first, these baths existed only in the immediate neighborhood of natural thermal springs, the hot vapors arising from which were confined within a superimposed chamber. From the same quotation we glean the further information that dry heat produced through the agency of hot sand or the laconicum, was also utilized to promote perspiration, an anticipation evidently of our modern hot air baths.

According to Vitruvius, and as we see from the quotation from Celsus given above, such superstructures existed at the famed spa Baiae, while the latter adds that certain caverns in the Cumaean Mountains were also in request for the same purpose, the inclosed recesses of which were permeated with the vapors of thermal springs piercing the subjacent earth. Indeed, examples of such natural hot vapor chambers are still to be seen in the environs of Pozzuoli, i. e., the Bagni di Nerone, and also at Monsummano in the province of Lucca. The ruins of similar structures have been unearthed in the East, also in our own country at Bath.

To continue, the Romans in accordance with their usual custom, erected these "sweating houses" in all the countries that came under their sway, hence the widespread distribution of these remains of a bygone civilization. How it came about, that these Roman bathing establishments, despite their obvious therapeutic value, were allowed to lapse into disuse and decay is difficult to understand, but the fact remains, that with the decline of the Empire their use became obsolete, remaining so for many centuries to follow. The popularity of the vapor bath in Europe during the Middle Ages was in some measure due to the Crusaders, who introduced it from Palestine, and Baas in his *History of Medicine* remarks on the socalled sweating houses attached to almost every city of note throughout the Continent. In our sketch of the development of the system of vapor baths, we have seen that probably in the first instance the ancients contented themselves with utilizing natural sources of heat.

Obviously, however, this method had the great disadvantage that nothing in the shape of vapor bath could be enjoyed save in the immediate vicinity of a natural thermal spring. In order, therefore, to render their enjoyment of such baths independent of locality, they had to resort to artificial modes of obtaining the heat requisite for rude sweating chambers. The difficulty of maintaining a more or less constant temperature still confronted them, a disability they were destined to labor under up to the time of the introduction by the Greeks of their so-called hypocaust.

In conclusion, as may be gathered from the foregoing historical résumé, this particular bath would appear to represent the earliest effort of mankind to attain to a more specialized form of hydrotherapy.

As we have seen, alike by savage tribes and highly civilized nations, was its high therapeutic value recognized and though for some unrevealed reason, the old Roman vapor baths fell for centuries into ill merited desuetude, yet it never lost its hold upon Eastern nations, among whom it persisted as a Mahommedan survival of the old Roman baths.

Kidney Physiology and Anatomy According to Hippocrates and Aristotle

JONATHAN WRIGHT, M.D.,

Pleasantville, N. Y.

(*Concluded from page* 30)

This matter has been more or less developed in the literature of the history of medicine, but there is a matter which has engaged my attention since I have rummaged through ethnological literature in search of the medicine of primitive man which has a connotation with the early history of the function of the kidneys and this is one which has received so far as I know no attention from medical historians. This is the superstition prevailing among the primitive Australians, and elsewhere at least to some extent among primitive men in Africa in regard to the kidney fat. This among the natives of Australia (5), who must now be spoken of in the past tense, was the much coveted object desired by all those wanting to work magic. On the other hand it was treasured by each man as the most essential part of his anatomy, the loss of which at the hand of another, however slight the wound in extracting it, was a certain and unavoidable harbinger of death. However robust he simply gave up all hope or desire for life and died. When in the bush he was constantly on the alert lest some enemy lurking in secrecy, or the companion walking at his side, finding an opportunity too tempting, should crack him over the head and before he recovered his senses, with a sharp flint knife would make an incision and extract from him the very fountain of life. It is conceivable of course that in this lightning like assault and savage surgery the suprarenals were frequently enough injured or torn out to give rise to the absolutely assured presentment of death in the victim. The assailant often had no personal grievance

against the man. He was only a primitive experimentalist engaged in research with magic as his dominant theory and with his specimen he retired to the depths of the forest and worked for the salvation of his patients or perhaps more often for the destruction of his foes. I am sure no candid researcher now, after the recent unpleasantness among civilized and cultured men, can criticize our savage progenitor for doing his part in the preparation of munitions for his tribe intending to exterminate some other tribe.

Here, however, our interest is to lead up to what Aristotle has to say about the kidney fat. "Of all the viscera the kidneys are those that have the most fat. . . . The fat is not formed in the kidneys themselves, the density of their substance forbidding this, but is deposited about their external surface." It acts as a cushion allowing of the flexibility of the loin and yet protecting very important organs from injury, other vital organs of the various cavities being protected by bony walls or musculature. It also maintains the animal heat. The kidneys "are organs through which the residual matters percolate, . . . moreover by being fat they are the better able to secrete and concoct their fluid" (6a). It will be seen that while Aristotle attributes special functions to the fat around the kidneys, he has missed the magic his primitive predecessors and his modern descendants and disciples have found in it, when it contains the suprarenals at least, but it lends emphasis to his appreciation of the importance of the fat to see he regards that in which the kidney is embedded as distilled from it.

In drawing upon modern ethnology for examples of prehistoric primitive man we are inadvertently betrayed into the error of assuming that as primitive man is now so he was when sprang away from him those marvelous ancient civilizations whose thoughts, if only out of mere curiosity, we are so eager to share. It may be "in vain we hope to be known by open and visible conservatories when the unknown was the means of the preservation of the relics of the past and obscurity their protection," but at the dawn of recorded consecutive thought it is quite impossible to enter into its ancient current without speculating, without forming at least some tentative opinion whence it flowed, and the quotation I have elsewhere (8) made from a spurious book of Galen in regard to the magic of his day is a hint we may not be far wrong. We perhaps have gained little from our comparatively modern knowledge of the Australian bushman as to the ideas of the kidney fat and we can perhaps not hope to fathom the reasons why Aristotle thought of the bladder as being the chief organ for secreting the urine from the blood. It seems, however, we do get in line with some ancient primitive theory when we find Aristotle saying, the spleen drawing water from the stomach and the kidneys being absent in birds and most reptiles and the flesh itself separating water from the food, "the kidneys, when they are present, exist not of actual necessity, but as a matter of greater finish and protection" (6b), they are of assistance to the bladder, both existing for the same purpose. Only those animals whose lungs contain blood have a bladder. The same is true of the kidneys (6c). We need not stop to point out the mistakes of Aristotle on this subject, but we see how the mistaken theory of the function of the urinary organs arose out of his extensive and direct observations upon animals, in part, but apparently in part only.

What we have found in the Hippocratic Corpus both as confirmation and refutation of the theory so clearly enunciated by Plato and what we have gathered from Plutarch point to the existence, as late at least as the reputed epoch of Hippocrates, of a body of belief that the fluids, taken in by the mouth and passing through the lungs and the flesh elsewhere as filters, passed by different channels than the kidneys to the bladder. Notwithstanding this aberration and its origin in preexisting thought we find Aristotle observing (6c) that "the duct which runs to the kidney from the great vessel does not terminate in the central cavity but is expended in the substance of the organ, so that there is no blood in the cavity nor is any coagulum found after death. A pair of stout ducts void of blood run from the cavity of each kidney to the bladder." Whether he is referring to the renal vein coming off from the vena cavity as the duct going to the kidney is not very clear, but in all probability that is his thought, for he believed the arteries in general to be free from blood. So apparently did the author of the Hippocratic book on *Anatomy* (2a) who uses the word bronchus. The latter dwelt in an obfuscation which concealed from him any functional difference between a bronchus and a large artery. Before Aristotle the word aorta had not the specific application in anatomy which he first gave to it. There is therefore no difficulty in perceiving the conception existing of water poured into the lungs going more or less directly without the intervention of kidney or bloodvessel to the bladder.

From this more or less naive conception arose later mistaken conceptions of function and its disturbance even in Galen, who knew vastly more anatomy of man though he gained it from apes, than Aristotle did. But Galen gets from Aristotle and Aristotle had it from his extensive dissection of animals that in man the right instead of the left kidney is higher in the abdominal cavity than the left. He knew, too, as we see in his *History of Animals* (7) that "both the aorta and the great vein continue as far as the kidney each as a single duct," that there are "branches near the kidney both from the great vein and the aorta," but what experience led him to the succeeding statement it is difficult to say: "two other strong and continuous passages reach from the aorta to the bladder and others from the cavity of the kidney, but these do not communicate with the great vein." These continuous passages from the aorta to the bladder must have been arteries and if arteries carry nothing but air it is difficult to see how the bladder is going to distil urine from the blood by virtue of their existence. Evidently then Aristotle had some other use for them or there is some mutilation of the original text. I have used Creswell's translation. It agrees with that of St. Hilaire. The text of Scaliger edited by Schneider justifies it. If the bladder is a secreting organ in the physiology of Aristotle it has nothing to secrete from. What the two large continuous arteries were one better skilled in comparative anatomy must say, and Dr. Singer has made a study of the anatomy of Aristotle. As

this is a side issue to our interest in the kidneys, I may be permitted to leave the matter there, but before doing so it is well to remark that Aristotle rejected (6d) the idea of fluid passing normally into the lungs, possibly also having the erroneous statement of Plato in mind.

Contributors to the Science of Medicine

EDWARD JENNER

Edward Jenner was born on May 17, 1749, at Berkeley, Gloucestershire. His father, who died when Jenner was a small child, was the vicar of Berkeley, and his mother a member of one of the oldest and most prominent families of Berkshire. Edward's education was supervised by his older brother, the Reverend Stephen Jenner; his favorite studies were the classics and natural history, his bent toward the latter having shown itself at a very early age. At the age of nine he had already made a sizeable collection of dormouse nests, and was spending most of his time hunting for fossils in the neighborhood of his home.

When he was quite young his profession, according to the English custom, was decided upon and medicine chosen. To begin the acquirement of knowledge of this subject, he was apprenticed to a physician, and, after completing his term of service, went to London to continue his studies, where he lived for two years in the family of John Hunter, whose favorite pupil he became. This friendship lasted throughout the lives of the two great physiologists, for they had many interests and traits of character in common.

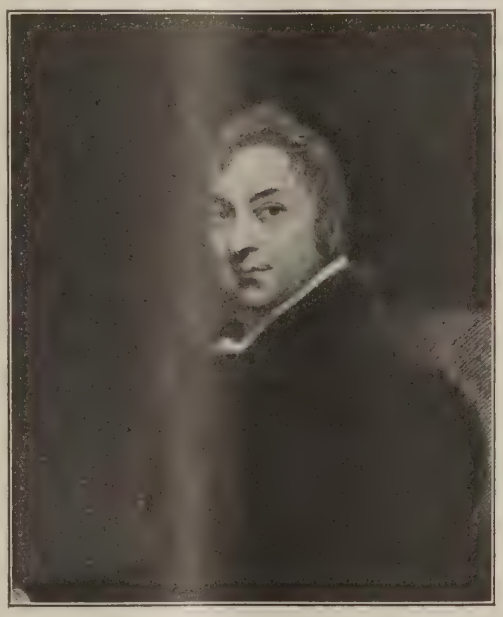
Because of Jenner's almost unparalleled skill in dissecting and mounting anatomical and natural history specimens, Hunter recommended him to Sir Joseph Banks to prepare and arrange the large number of specimens brought home by Captain Cook from his famous voyage of discovery in 1771. The next year he was invited to become the official naturalist of the succeeding expedition, but declined, preferring for his work the seclusion of a country village. It is to this decision that we probably owe one of the greatest benefits the medical profession has ever given to mankind—the demonstration of the prophylactic powers of cowpox and vaccination. This subject became Jenner's hobby; it is said that he imposed it upon the medical club of which he was a member to such a harassing degree that he was threatened with expulsion because he insisted upon dinning into their ears a theory which they conceived to be without any foundation but popular rumor. Jenner therefore had to carry on his investigations alone and without any sympathy from most of his colleagues. He succeeded in perfecting his inquiry amidst the many and anxious duties of the country practitioner, although he was more than fifty years of age before he published in full the report of his experiments and investigations.

While he was still an apprentice, a young country woman applied to his master for advice. Smallpox was suggested, to which she replied that she could not take that disease since she had had cowpox. Jenner never forgot her remark, and the incident, insignificant as it was, led to his future work with vaccination. His concealment of his results did not rise from selfish motives, but, first, from the lack of sympathy which he met with from members of his own profession; and second, a fear of disappointment or failure, if the matter should be brought out too early to carry immediate conviction with its publication. One of his early discoveries was that swinepox as well as cowpox is a variety of smallpox. This he found out through inoculating his oldest son with swinepox virus. He discovered also that cowpox does not always give immunity against smallpox, which led to a series of experiments that finally demonstrated that it is only in a certain state of the vesicle that the virus possesses protective power. His first successful vaccination was performed on May 14, 1796, when he injected lymph from the arm of a woman infected with cowpox into the arms of a healthy boy of eight. The boy had cowpox, and on July 1st was inoculated with smallpox, with no effects.

Jenner expressed his joy and satisfaction with the results of his labors as follows: "While the vaccine discovery was progressive, the joy I felt at the prospect before me of being the instrument destined to take away from the world one of its greatest calamities, blended with the fond hope of enjoying independence, and domestic peace and happiness, was often so excessive that, in pursuing my favorite subject among the meadows, I have sometimes found myself in a kind of reverie. It is pleasant to me to recollect that these reflections always ended in devout acknowledgments to that Being from whom this and all other mercies flow."

In 1798 Jenner went to London for the purpose of demonstrating his discoveries to his professional friends, but his proposition was received with so great apathy and distrust that he was forced to return to his country home without having made a

single inoculation. The virus brought to London with him, however, he consigned to the celebrated surgeon of St. Thomas's Hospital, Dr. Cline, who finally inoculated some children with good results. Thus the interest of the medical profession in the subject was aroused, and many physicians began to clamor for the opportunity to test the new virus. Jenner was summoned to return and offered a salary of ten thousand pounds if he would settle and practise in London. This was the great naturalist's reply: "Shall I, who even in the morning of my days sought the lowly and sequestered paths of life, the valley and not the mountain; shall I, now my evening is fast approaching, hold myself up as an object for fortune and fame? Admitting it as a certainty that I obtain both, what stock should I add to my little fund of happiness? My fortune, with what flows in from my profession, is sufficient to gratify my wishes; indeed, so limited is my ambition, and that of my nearest connexions, that were I precluded from future practice, I should be enabled to obtain all I want. And as for fame, what is it? a gilded butt, forever pierced with the arrows of malignancy. The name of John Hunter stamps this observation with the signature of truth." Jenner never thought it necessary to reply to unfounded and harsh aspersions, for he was satisfied with the strength of his own case.



EDWARD JENNER

Among his first patients for vaccination were many persons of high rank, among them the children of Henry Hicks, of Lady Frances Morton, and of the Countess of Berkeley. He also vaccinated the children of William IV. He was supported in Parliament by Lord Sidmouth and the Duke of Clarence. In 1808 the National Vaccine Establishment was organized, where the practice of vaccination and the supply of lymph have even since been continued.

In 1788 Jenner married Catherine Kingscote, a woman of great intelligence and culture. Her death in 1815 was so great a blow that he gave up his work in London and retired to Berkeley to spend the remainder of his life. He died from apoplexy on January 26, 1823, in the seventy-fourth year of his life, and is buried in the chancel of the parish church at Berkeley.

Those who knew Jenner have written much about his great capacity for friendship and comradeship which led to his having spent most of his life surrounded by a loving and admiring company. Even on his walks he was usually accompanied by a host of friends who delighted to listen to his comments and talks on nature. He seems to have been able to combine to a remarkable degree a talent for the profoundest observation with a lively, happy disposition, and a real genius for imparting information with the greatest simplicity and originality. He was a poet of some merit and quite a wit. He sent the following lines, accompanied by a pair of ducks, to a lady whose daughter, a patient of his, had recovered from her illness:

> I've dispatch'd, my dear madam, this scrap of a letter
> To say that Miss ——— is very much better;
> A regular doctor no longer she lacks,
> And therefore I've sent her a couple of quacks.

Because of the success of his work, his social and intellectual accomplishments, and the charm of his personality, Jenner was much sought after for membership in many learned and scientific societies. The Empress Dowager of Russia sent him a diamond ring with a letter testifying to her great admiration for his work. She had the first child vaccinated in Russia named Vaccinoff, and fixed a pension upon it for life. Many honors were bestowed upon him, among them the mayorship of his own town. Through his high position Jenner was frequently able to accomplish much good other than that of a medical nature. The story is told that he was begged to appeal to Napoleon for the release of Dr. Wickham of Oxford who was held prisoner after the close of the war with France. Jenner sent a petition to Napoleon, in spite of the fact that the latter's attitude toward England was in its most hostile stage. The petition was presented to the Emperor while his carriage was changing horses at a post. He refused to look at it. "But do you see from whom it comes?" cried Josephine, "From Jenner." Bonaparte's voice at once softened. "What that man asks cannot be refused," he exclaimed, and the petition was immediately granted. A passport to a foreign country signed by Jenner was always certain of attention and respect. In fact, the cause of vaccination was much more quickly and ardently received on the continent than in Great Britain, and its practice was perfected and established much earlier than in the great scientist's native land. His recognition in England was not official until 1803, when the Royal Jennerian Society was established, having the king and queen for patrons, and various members of the royal family and nobility for its supporters. The purpose of this organization was to vaccinate the poor gratuitously and to supply the world with virus. It was dissolved in a few years because of dissension and differences among its members.

Thomas Joseph Pettigrew in his *Biographical Memoirs* describes Jenner as "void of ostentation, and of great simplicity of manners, he never courted popularity, or sought distinction. The approbation of the highest and of the most intellectual ranks afforded him gratification, but did not beget pride. One great object occupied his mind, and everything yielded to its accomplishment; that effected, his natural disposition immediately manifested itself and he returned to the country and courted retirement."

Editorial Articles

VOLTAIRE ON SMALLPOX

Like many other brilliant nonprofessional thinkers, Voltaire was a shrewd observer in matters of health, and his advice in such wise would have been of much more value than that of most physicians of his day. He had no reason for exaggerating the evil of smallpox, to which he devoted one of his "Letters on the English." He had no medicament to sell. "Upon a general calculation," he says, "threescore persons in every hundred have the smallpox. Of these threescore, twenty die of it in the most favorable season of life, and as many more wear the disagreeable remains of it on their faces as long as they live. Thus a fifth part of mankind either die or are disfigured by this distemper."

However, he goes on to say that "It does not prove fatal to as much as one of those who are inoculated in Turkey or in England, unless the patient be infirm, or would have died had not the experiment been made upon him. Besides, no one is disfigured, no one has the smallpox a second time, if the inoculation were perfect. . . . But are not the French fond of life, and is beauty so inconsiderable an advantage as to be disregarded by the ladies?

"It must be confessed that we are an odd kind of people. Perhaps our nation will imitate, ten years hence, this practice of the English, if the clergy and our physicians will but give them leave to do it; or possibly our countrymen may introduce inoculation three months hence, from mere whim, in case the English should discontinue it through fickleness."

If the English took readily to inoculation, they have not been very thorough in more recent years with regard to vaccination. From January to May over fifteen hundred new cases were reported for England and Wales and, according to the person reporting, it is "obvious that smallpox is steadily regaining its old ascendency in this country. Its mildness, too, is beginning to change a little. Unless measures far more drastic than any heretofore put into force are taken, a great catastrophe may lie ahead."

In our own country the number of cases this year is alarming and promises to be much larger than it was last year. There is respect for vaccination only in spots. We are told that in Philadelphia, thanks to "rigid observance of school vaccination laws, smallpox in a native of that city is absolutely unknown" but in Tennessee, out of 790 children examined in the rural schools, "only forty-eight, or about six per cent., had been vaccinated." Even in a city like Detroit there is now a "normal" case rate for the disease.

Voltaire's remark about the fickleness of the French in not making use of inoculation may help to explain the nonuse of vaccination by many persons and groups of persons in this country. If one could join some exclusive order by being vaccinated, no doubt we would all go to the trouble, or if it were a more expensive performance many antivaccinationists would find it worth while.

When one considers the danger incurred by our ancestors in being inoculated with the disease we are even more convinced of its terror than by Voltaire's statistics, startling as they are. And when we compare the age of vaccination with that of inoculation we can thank our stars that we live neither before nor during the age of inoculation.

ANTHROPOLOGY OF THE HUMAN EYE

From the viewpoint of distinction between races and the determination of individual types, the orbit offers many interesting points, such as the height occupied by the orbits in the skull, the degree of the nasoocular angle, the direction of the great axis of the orbital opening, the interorbital distance, and the degree of the orbitooccipital angle. A more detailed study of the orbit, considered in respect to its internal and external shape, is likewise useful. From this study an essential difference is found between the yellow and white races, the orbits of these respective races presenting notable divergencies, between which other races may be classified. The yellow and the white races by their orbits constitute two distinct types, around which are grouped other types presented by various races and known human species.

This fact becomes more evident when the eyelids and palpebral cleft are considered, and here especially, two distinctly defined types are found, viz., the European or white, and the Mongol or yellow. The European eye is erect, well opened with smooth eyelids, and with everted normally developed lashes. The Mongol eye, on the contrary, is small, half closed, frequently oblique, with swollen, bridled eyelids, the upper lid inverted with atrophied lashes. It is also a fact that some of the peculiarities of the Mongol eye are encountered in the European, but this is exceptional and would seem to prove the common origin of all the human races, which afterwards

became separated and diversified, gradually losing the common characteristics. There exist other types of eyes, such as the American Indian, the Australian, and the Laplander, but their importance is far less than in the preceding types and their characters are not so well defined.

Considering the globe of the eye, it will be found that the principal classification between the two types —white and yellow—no longer maintains. Pigmentation is here all important, and it is the two extremes—white to black—that must be considered. Between these extremes are placed yellow, red, brown, and blond.

The globe of the eye is one of the regions of the body which bears evident marks of general pigmentation. The sclerotic is more or less tinted, while the iris offers much the same coloring as the skin and hair of the subject. The importance of this characteristic has been accepted by anthropologists and in many countries attempts have been made to draw up exact charts of distribution of color, and in Europe, particularly, the results have been conclusive, such, for example, as Topinard's color (human) chart of France. To the maximum pigmentation of the negro might be opposed the characteristic pigmentation of the albino, but this is not valid because albinism is to be regarded as a pathological process and not the lowest degree of the color scale, the negro representing the highest.

Generally speaking, anthropologists have rather neglected refraction and ocular pathology, although some observers have been struck by the influence exercised by the confirmation of the skull over ocular refraction. The anthropological study of myopia and astigmatism has received some attention, especially by Nimier, who has published some interesting data in respect to racial influence in the production of these defects, especially in France, but hypermetropia has, as far as we are aware, been disregarded.

It is hardly necessary to recall the manifest influence of the race in the production of myopia or the hypotheses of Javal and Wecker, according to whom the study of astigmatism will reveal the shape of the skull of the inhabitant of a given country by a mere inspection of their handwriting.

Ocular pathology has also been neglected by anthropologists, although it is clear that in this case the question of race is quite accessory, while individual influence is preponderant. However, it would seem that trachoma and glaucoma occur preferably in certain races, as the researches of Wecker and Chibret seem to show. It is to be hoped that further anthropological researches in respect to the eye, its anomalies and pathology, will be forthcoming, as the subject is an important one.

GASTRIC ULCER AND CANCER

Opinions among surgeons and radiologists differ widely with regard to the frequency of cancer of the stomach originating from or superimposed upon gastric ulcer. Many great surgeons hold that gastric ulcer has nothing to do with the causation of cancer; others hold that the evidence in support of the relationship between cancer and ulcer is not convincing; while yet others assert that gastric ulcer is a comparatively frequent exciting cause of cancer.

At the annual meeting of the Minnesota State Medical Association, held in St. Paul in October, 1923, a paper was read on Factors of Safety in Gastric Surgery by Dr. Donald C. Balfour, of the Mayo Clinic, and published in *Minnesota Medicine* for May, 1924. In the discussion that followed, Dr. William J. Mayo, of Rochester, had this to say with regard to the question of cancer on ulcer. His experience was based, not on all patients who came to the clinic, but on the patients who were actually operated upon for cancer of the stomach. The Mayo Clinic had been quoted as saying that seventy-one per cent. of cases of cancer of the stomach had their origin in ulcer. He doubted whether even twenty-five per cent. of the cases of cancer of the stomach observed consecutively could be actually shown to have their origin in ulcer, but that ulcer of the stomach was a serious disease, more serious than ulcer of the duodenum, and often preceded cancer.

They did not doubt, he went on to say, that the great insurance companies were anxious to know whether patients on whom operation had been performed for ulcer of the stomach and duodenum were insurable and Mr. Hunter, the vice-president of the New York Insurance Company, came to the Mayo Clinic and with his own actuaries investigated the records of about three thousand patients who had been operated upon for ulcer of the stomach and duodenum. Then through the medical examiners of the life insurance companies, these patients were traced, and as far as possible, examined; thus accurate data were obtained concerning the actual results. They were able to trace about ninety per cent. of the patients, and found that five years after operation on the duodenum for peptic ulcer, the death rate was if anything less than among the average insurable persons of the same age. The death rate five years after operation for ulcer of the stomach was two and a half times more than the normal death rate at the same period of the average insurable persons.

Dr. Donald Balfour supplemented the remarks of Dr. Mayo as to the study made by the actuarial society. He took occasion, when the report came out, to investigate as well as he could the cause of death in the gastric ulcer group, and it was astonish-

ing to learn of the number of patients who died of cancer afterwards. And then as the operative records of the patients who had died from cancer were reviewed, it was found that a large proportion had only had a gastroenterostomy done for a large irremovable lesion, presumably gastric ulcer. The lesion was usually to the pancreas, and the surgeon felt that it was not possible, or not feasible, to attempt to get a section of it. Those patients did well for a few months, then began to lose ground, and a report came within one year or two years that they had died from cancer. It is reasonable to suppose that these patients had cancer at the time they were operated upon. If that group is eliminated from the entire group of patients who have died after operation for gastric ulcer, it would be found that the expectation of life was much better than was found by the actuarial society.

While it has not been conclusively proved that cancer does follow gastric ulcer in a goodly proportion of cases, evidence seems to point that way. Even if the group of cases which Doctor Balfour believes, and apparently rightly, were cancer at the time of the first operation, be removed from the list of fatalities in the report of the actuarial society, the death rate of the gastric ulcer group will still considerably exceed that of the duodenal ulcer group, and there will be left a proportion of cases in which the patients died from cancer. If cancer is due to chronic irritation, it appears plausible and even logical to argue that a longstanding gastric ulcer is a source of chronic irritation and is apt to act as the exciting cause of malignant growth in a person susceptible to cancer, that is to say, if we grant that an individual may inherit a predisposition to cancer.

CANCER OF THE COLON AND ITS POSSIBLE CAUSES AND TREATMENT

There is no agreement between members of the medical profession as to the cause or causes of cancer of the colon. At the present time there is a large number of medical men in this country and Great Britain who hold that chronic intestinal stasis is a cause of cancer of the colon as it not only supplies the irritative factor which is universally believed to be the exciting cause, but also because the alimentary toxemia brought about by prolonged retention of waste food products in the intestine poisons and devitalizes the system and renders it less able to resist successfully the attacks of disease.

The article by Dr. E. G. Slesinger in this issue supports this point of view. He says "it is difficult to escape the conclusion that the obstructions to the passage of the contents of the bowel which develop in nature's attempts to hold up the heavy constipated colon represent the irritative factor in the production of cancer which is so clearly recognized in the cancers of the mouth and skin." If then it be allowed that irritation consequent upon chronic intestinal stasis may occasion cancer in those susceptible it seems obvious that in many cases the disease may be prevented by not permitting constipation to reach the stage of chronic intestinal stasis by careful diet and habits of life generally and by maintaining free elimination.

If the condition has continued too long and a malignant growth has formed, of course the only treatment calculated to relieve is operative. Dr. Slesinger describes measures in the early stages when the patient has been lucky enough to have his symptoms diagnosed correctly at that stage, and operative measures at later stages varying to some extent with the progress of obstruction and with the location of the growth. He does not hold with the usual operative procedure for cancer of the colon and explains why and clearly describes the operation preferred and practised by him. But Dr. Slesinger's paper deserves to be read and closely considered.

MAN AND ANIMAL

The fall of man considered physically is no myth; our sad array of clinics and hospitals is quite sufficient evidence. As J. Arthur Thompson has put the matter in a recent essay, "Wild Nature is all for health. . . . It is a remarkable fact that there is almost no constitutional disease in Wild Nature unless man has interfered. . . . Microbic diseases are rare, apart from cases where man has polluted the water or where he has altered the distribution and exposed animals to foes to which they are unaccustomed, as in the case of horses exposed to the trypanosomes of African horse sickness which the tsetse fly carries from some indigenous host, perhaps an antelope, to the newcomer.

"Many wild animals have their microbes and larger parasites, but the point is that a live and let live compromise tends to be established, and there is not what can be called disease. A few exceptions were known, such as bacterial disease of sandhoppers, but these cases may turn out to be less exceptional when our knowledge of them is more adequate. A grouse may have thousands of threadworms living as parasites in its food canal, but they do not seem to matter much unless the bird becomes, for other reasons, enfeebled. We may say, then, that outside of domestication and other forms of human interference, there is little in the way of microbic or parasitic disease in Wild Nature. Now and again the introduction of a new parasite may cause an animal

epidemic, and perhaps this is the explanation of the sudden disappearance of some species like the passenger pigeon in historic times. But wholesale infection is not likely to occur apart from man."

These remarks of the distinguished zoölogist may well make us blush for our kind, and contain food for thought for the hygienist and sanitarian.

"If there is almost no disease in Wild Nature," Thompson continues, "why does man show so much? The answer is manifold. a. Man is a restless exploring organism, and this means exposure to new microbes. And it is an invasion of the body by a microbe to which the tissues are unaccustomed that is so dangerous. The organism has or may have the ability to produce counteractives to certain microbes and parasites to whose intricacies it has been subject, but it may be unable to answer back effectively when a new invader appears.

b. "There is no getting past the fact that ambition or greed or dire necessity may lead a man to tolerate unwholesome conditions. He often stakes his health defiantly; he often stakes it in despair.

c. "Similarly, man's love of pleasure and his liking for narcotics and stimulants . . . lead, like artificiality of life in general, to conditions which favor the onset of disease.

d. " On a different plane is the fact that the general human inheritance is not in perfect harmony with the rapidly changing human environment. Our long drawn food canal was probably quite convenient when our ancestors had to eat much that was not digestible and had to make the most of a good square meal when opportunity offered, but it may be worse than inconvenient now.

e. "But there is a fifth reason, simply that it is not the human practice to select rigorously for health. . . . It must be admitted than man is a careless creature. With his head in the air he stumbles and comes to grief gratuitously."

For racial improvement Thompson offers the following general considerations: a. "The standard of health should be pitched high. We should cultivate not merely a respect for health, but an *enthusiasm*, and that enthusiasm must be loyal to the unity of the organism which is Body-Mind as surely as it is Mind-Body. . . . Respecting the unity of the organism justice must be done to the therapeutic value of the imagination. . . . That the limit of safety may be crossed by the fanatic at the one end of the inclined plane and the credulous victim of charlatanism at the other, is no argument for neglecting the use of our organs.

b. "The biological trinity, organism, function, and environment, or folk, work, and place, must be respected.

c. "Postponing the question of how far the stamina, the 'physique' *of the race* can be affected by changes in individual 'nurture,' we must point out here that there is no question as to the influence which improved 'nurture' may have on the 'health' and well being *of the individual*. Bad seed cannot be changed into good, but as far as the individual is concerned, buds of evil portent can often be inhibited and buds of good promise encouraged."

CURIOUS REMEDIES

It has been stated, perhaps with more truth than can usually be attributed to such tales, that both Washington and Cavour were killed by their doctors, as their medical attendants, in accordance with the custom of the times, bled them so that they died. Less than one hundred years ago bleeding was regarded as the panacea for almost all bodily ills and Lettsom, a great London physician, who founded the Medical Society of London, bled for all ills to which poor humanity is heir. He bled just as cheerfully and enthusiastically for apoplexy as for tuberculosis; the plethoric and the badly nourished received the same drastic treatment at his hands. Moreover, he was a firm believer in the method and is thought to have hastened his own end by cupping himself too freely and frequently. He was a thin, spare man.

There were medical practices more absurd by far than this, as on occasion bleeding did good. The great Dr. Johnson and his contemporaries held that a touch from a royal hand cured scrofula, which was known as the King's Evil, and Raymond Crawford, a physician of high repute, has written a fascinating book on the subject. Pepys, in his diary, refers to the queen's illness and says that "she had to be shaved, and pigeons were put to her feet." In country districts, medical superstitions linger long and in parts of Brittany a field mouse is looked upon as a cure for smallpox, a spider in a nutshell worn round the neck keeps away fever, three hairs from the cross on an ass's back will cure whooping-cough, though the ass will die. In England and in New England snails used to be highly esteemed as valuable in the treatment of consumption, and when boiled in barley water were held to cure an ordinary cough. Should a sixteenth century person be afflicted with warts, then according to the book of charms "Put three droppes of the blood of a wart in an eldern leaf and burie it in the earthe and the warts will vanish away."

An extraordinary remedy for gout was to place flowers of the lily of the valley in a bottle, bury the bottle in an ant heap, and then after a month, unearth the bottle, and the liquor found inside would be a perfect cure. Readers of Beaumont and

Fletcher's comedy, *Knight of the Burning Pestle,* will call to mind the instructions given to sufferers from chilblains, namely, to rub the feet well with a mouse's skin and to roll the feet and ankles in hot embers.

Quacks and sometimes even real physicians seem to have had faith in the efficacy of mumbled incantations and charms. A victim of burns by fire was advised to mumble:

> There came three angels from the East
> The one brought fire, the other brought frost.
> Out fire; in frost;
> In the name of the Father, Son and Holy Ghost.

Of course, there is a psychology of medical superstition, and in certain cases the mental influence was sufficient to improve the physical condition.

NEAR EAST RELIEF MEDICAL WORK.

The Near East Relief has recently issued in pamphlet form a report of its accomplishments in Asia Minor and the Caucasus. This report shows what a tremendous amount of persevering effort is necessary in carrying on the work of such an expedition. The Near East Relief medical organization was sent into Turkey soon after the Armistice to care for the cases of starvation, illness and injury, with Dr. George H. Washburn as its medical director. The plan was to use existing missionary hospitals. It was found that these were not only practically without equipment, but were in such bad condition that much repairing had to be done before they could be used. The first hospital unit dispatched from Derinje to Constantinople consisted of two trains, carrying the relief workers and supplies. The party lived in the freight cars and cooked for themselves. As progress was made toward the interior, portions of the supplies were left at various places where it was deemed advisable, and safe, to establish hospitals.

The report says: "This initial journey among the field stations made the way easier for the progress of the work. Some of the hospitals were two hundred miles or more from the railroad. Medical consultations in the ordinary sense were of course impossible. The doctors had to be capable of taking responsibility and acting with discretion, and at the same time to be equal to all kinds of emergencies. Tact and firmness were necessary to deal with the disordered conditions then and now present in Turkey. Cholera appeared in one of the cities of about forty thousand inhabitants. Ordinarily, when cholera starts in the Orient, it goes on for some time and takes a large toll in lives. The Near East physician in this city went at once to the authorities and received permission to use cholera vaccine in the quarter of the city where the epidemic started. About a thousand people were vaccinated in forty-eight hours and the cholera epidemic stamped out."

The report outlines work at the various units established, three of which were at different times in charge of Dr. Mabel E. Elliott, whose book, *Beginning Again at Ararat,* has already been reviewed.

Obituary.

BEVERLEY ROBINSON, M.D.
of New York

Dr. Beverley Robinson, senior consulting physician at St. Luke's Hospital, New York City, died at his residence, 129 East Thirty-fifth Street, on Saturday, June 21st, of arteriosclerosis and heart disease. Dr. Robinson had been a member of the visiting staff of St. Luke's for more than forty years. He was born in Philadelphia in 1844 of distinguished ancestry. His father was Moncure Robinson, builder of the Philadelphia & Reading Railroad, and on his mother's side he was the great grandson of Edmund Randolph, first Attorney General of the United States.

After being graduated from Princeton University in 1862, Robinson joined the State Militia and fought in the Gettysburg campaign. Later he went to Paris to study medicine, and was the first American to be graduated from the university there. In 1872 he received his medical degree with honors from that institution, and in 1873 came to New York, where he made his home for the rest of his life.

Dr. Robinson was attending physician at several of the leading hospitals of New York besides St. Luke's, and for many years was professor of clinical medicine at Bellevue Medical School. He was one of the founders of the Association of American Physicians, and at one time president of the American Climatological Association. During the World War, he was one of six American doctors to receive an honorary medal from the Faculty of Medicine of Paris.

His best known works are probably the *Treatment of Ordinary Diseases,* and *Essays on Clinical Medicine.* He was also the writer of numerous articles and papers on various medical subjects. Even during his last years, Dr. Robinson retained his interest and kept up his studies in medical science. His death is a great loss to his profession.

News Items

Medical Fellowship.—Dr. Arthur M. Master, of New York, has been awarded the Cornell University Traveling Fellowship in Medicine for the year 1924-1925.

Essay Contest.—The *Modern Hospital* offers cash prizes of $350, $150, and $100, for the best essays on the subject of Interrelationship of Hospital and Community.

Prize Award.—Dr. Evelyn Holt, of this year's class of the Cornell University Medical College, who received the John Metcalf Polk prize of $300, has been appointed as an intern in the New York Hospital, the first woman to receive this appointment.

Lunacy Law Amended.—According to the amendment of the New York State lunacy law, persons alleged as insane criminals must be sent to the observation ward of Bellevue Hospital or Kings County Hospital, instead of tested by lunacy commissions appointed by Supreme Court Justices or county judges.

Smallpox Cases.—The *Public Health Bulletin* reports 1,292 cases of smallpox in the registration area for the week ending June 7, 1924, contrasting with 474 cases in the corresponding week last year. The number of cases increased also from the preceding week in 1924. Thirteen deaths from the disease occurred during the week of the report.

Stream Pollution.—The States of Ohio, Pennsylvania, and West Virginia, have agreed to cooperate in the prevention of stream pollution.

Ammendments to Sanitary Code.—The State Sanitary Code of New York, Chapter II, was amended in various ways at the meeting of the Public Health Council held at Saratoga Springs the last of June. These amendments concern communicable diseases.

Shriner's Hospitals.—The Shriners are ambitious to build at least twenty hospitals for crippled children, and have already in operation such hospitals at San Francisco, Portland, Oregon; Shreveport, and Minneapolis, with another in St. Louis, recently dedicated. Construction is going ahead on the buildings at Montreal and at Springfield, Massachusetts, and land has been purchased in Philadelphia and Chicago. Two dollars a year is collected from each Shriner for the support of these hospitals, and treatment for orthopedic defects is given regardless of creed or race, the only provisos being that the child must show reasonable chance of cure and that its parents are unable to pay for treatment in other hospitals.

Activities of Medical Schools.—The St. Louis University School of Medicine has taken full control of the medical and educational activities of the St. Marys group of hospitals, comprising six hundred beds, which will become the University Hospital. The department of medicine has been organized on a full time basis.

Several Cleveland institutions are negotiating a merger with Western Reserve University to form a University of Cleveland. These include Case School of Applied Science, Lakeside Hospital, Maternity Hospital and the Babies' Hospital, the Cleveland Museum of Natural History, the Cleveland School of Art, the Cleveland Museum of Art, and the Western Reserve Historical Society Museum. An endowment fund of $20,000,000 is planned for.

The State University of Iowa is to have a new $4,500,000 medical building, made possible by the State appropriating funds to equal a gift of the Rockefeller Foundation. The site is near the new children's and psychopathic hospitals and the new nurses' home.

The University of Indiana Medical School has received a gift of $75,000 from Mr. and Mrs. William Coleman, as a memorial to their daughter. The gift will be used for the endowment of chairs of ophthalmology, surgery, and gynecology.

The Carnegie Corporation has granted $20,000 annually for two years to the University of Louisville Medical Department, to be used largely in developing the department of pediatrics.

Personal.—Dr. Claude Régaud, director of the Paris Radium Institute, who was in this country to attend the meeting of the American Medical Association, was entertained at dinner at the Hotel Commodore by the New York Röntgen Society and the staff of the Memorial Hospital.

Dr. Frank Billings, of Chicago, has been awarded the honorary degree of Doctor of Science by the University of Wisconsin.

Dr. Lillian Welsh, of Baltimore, has received the honorary degree of LL.D. from Goucher College, to commemorate her retirement after thirty years on its faculty as professor of physiology and hygiene.

Dr. William N. Wishard, professor of genitourinary surgery at the Indiana University School of Medicine, has recently been honored by the degree of Doctor of Laws by that institution. On the occasion of the fiftieth anniversary of his graduation, he was guest at a testimonial dinner given by the physicians of Indianapolis.

Dr. Harry Plotz, of New York, who is in Paris assisting Professor Besredka, has been made a member of the staff of the Pasteur Institute of Paris.

Dr. William W. Herrick, professor of clinical medicine at Columbia, has been elected president of the Association of Yale Alumni in Medicine.

Dr. George K. Meynen has been appointed surgical director of the Mary Immaculate Hospital of Jamaica, New York, and Dr. Charles A. Ross, its medical director.

The University of Pennsylvania has conferred the degree of Doctor of Science on Admiral Edward R. Stitt, Surgeon General of the Navy, and on Dr. James T. Priestley, of Des Moines.

Tropical Health Problems.—Health problems in tropical America are to be discussed at a conference held under the auspices of the medical department of the United Fruit Company, from July 22d to August 7th, at Kingston, Jamaica.

Civil Service Examinations.—The United States Civil Service Commission announces open competitive examinations for bacteriologist (medical), salary $3,000, and junior bacteriologist (medical), salary $1,740. Vacancies are at the Hygienic Laboratory, Washington, D. C. Application blanks may be obtained from the United States Civil Service Commission, Washington.

The Civil Service Commission of the State of New York announces examinations for pathologist, first assistant grade, State Hospital Commission, salary $2,700 to $3,300; and supervisor of physical education in State hospitals, State Hospital Commission, salary $2,500. For application blanks, address Examination Division, State Civil Service Commission, Albany, N. Y.

Society News.—The Iowa Clinical Medical Society has elected the following officers: Dr. Charles A. Waterbury, Waterloo, president; Dr. Frederick G. Murray, Cedar Rapids, vice-president; Dr. Russell C. Doolittle, Des Moines, secretary-treasurer.

The State and Provincial Health Authorities of North America have elected Dr. James A. Hayne health commissioner of South Carolina, president; Dr. Byron U. Richards, secretary of the Rhode Island Health Commission, vice-president; and Dr. Richard M. Olin, state health commissioner of Michigan, secretary-treasurer.

The American College of Radiology has elected Dr. William H. Stewart, New York, president; Dr. Samuel B. Childs, Denver, president-elect; Dr. Preston M. Hickey, Ann Arbor, vice-president; and Dr. Albert Soiland, Los Angeles, secretary.

The American Otological Society has elected the following officers: Dr. Eugene A. Crockett, Boston, president; Dr. Philip D. Kerrison, New York, vice-president; and Dr. Thomas J. Harris, New York, secretary-treasurer.

Staff Changes at the Rockefeller Institute.—The Board of Scientific Directors of the Rockefeller Institute for Medical Research announces the election of Dr. Francis Gilman Blake as a member of the Board of Scientific Directors to succeed Dr. Hermann M. Biggs, deceased.

Promotions: Associate members to members, Dr. James B. Murphy and Dr. John H. Northrop; associate to associate member, Dr. Thomas M. Rivers; fellow to assistants, Miss Gladys Bryant, Dr. Charles Korb, Miss Dorothy Loomis and Dr. Elmer L. Straub. Dr. William S. Tillett has been appointed Resident Physician at the Hospital.

New appointments: Assistants, Dr. Douglas Boyd, Dr. Clifford L. Derick, Dr. Louis A. Julianelle, Dr. Ann G. Kuttner, Dr. John F. McIntosh and Mr. Bernard J. C. Vander Hoeven; fellow, Dr. David Davidson.

Dr. Paul E. Howe, hitherto an associate in the department of animal pathology, has accepted an appointment with the Division of Animal Husbandry, Bureau of Animal Industry, U. S. Department of Agriculture, in charge of nutrition investigations.

Dr. George R. Brow, hitherto an assistant in the department of the hospital, has accepted an appointment as research assistant at the University College Hospital, London, under Sir Thomas Lewis.

Dr. Geoffry C. Linder, hitherto an assistant in the department of the hospital, has accepted an appointment at St. Bartholomew's Hospital, London, under Professor Francis R. Fraser.

Dr. Hugh J. Morgan, hitherto an assistant and resident physician at the hospital, has accepted an appointment as associate professor of medicine at Vanderbilt University.

Dr. James M. Neill, hitherto an assistant in the department of the hospital, has accepted an appointment as associate professor of bacteriology at Vanderbilt University.

Dr. Harald A. Salvesen, hitherto an assistant in the department of the hospital, has accepted an appointment as chief of clinic at the physiological institute, University of Christiania, Norway.

Foreign Correspondence.

LONDON LETTER

(From our own correspondent)

London, *June 14, 1924*

ACTIVE MOTION IN RELATION TO INJURY AND DISEASE

Among the changes in surgical treatment brought about in modern times no more radical change has been introduced than the treatment of fractures and sprains as well as many postoperative conditions by mobilization. In the old days an axiom in the treatment of fractures and conditions of a somewhat similar nature was that immobilization was indicated. This method was adhered to rigorously nearly up to the time of the war. However, at the present time active exercise is regarded by many leading surgeons as a *sine qua non* of successful treatment. Among the pioneers of this new departure is Mr. J. W. Dowden of Edinburgh, who at a meeting of the Edinburgh Medico-Chirurgical Society held on June 4th last, read a paper on the subject. Mr. Dowden said that a study of the anatomy and physiology of injury pointed to active exercise as the best remedy, not only for such conditions as fractures and sprains, but in many postoperative conditions, such as infected joints, infected tendon sheaths, cellulitis, and suppuration. Action movements were essential and should be commenced at once and carried out up to the point of producing pain. The patient must be encouraged daily to persevere in using his own muscles and his own brains. Passive movement and massage were not enough. He was accustomed to commence active movements within twenty-four hours and it was remarkable how quickly the patient gained confidence and to what an extent the range of movement increased in a short time. By this means the tone of the muscles was kept up, adhesions were never allowed to form, and by the active contractions of the muscles the injured bones were gradually welded into shape and, in cases complicated by suppuration, the accumulating pus was driven from the wound. By following up cases for several years Mr. Dowden was able to show how perfect a functional result could be obtained, and x ray examinations revealed no sign of previous injury to the bones.

DIET IN MEDICINE

At the same meeting Dr. D. Murray Lyon read a paper on the Rôle of Diet in Medicine. It may be said that the rôle of diet both in preventing and successfully treating disease has never been so well understood as at the present time, for the reason that it has never been on so scientific a basis. It is claimed by some that diet is chiefly responsible for most of the chronic diseases of civilization and that the salvation of the human race under civilized conditions depends almost wholly upon suitable food. However, it should always be borne in mind that the personal equation must be taken into account, a point which is too apt to be overlooked. Also the manner and habits of life. One thing seems to have impressed itself on the minds of those who have made a careful study of the question, that the vitamine element of food must be present in sufficient quantities. Therefore uncooked vegetables and fruit should make a part of the regular diet. Dr. Lyon pointed out that dieting had proved of paramount importance in diabetes. Allen had taught us the enormous importance of regulating the diet. Dr. Lyon discussed some of the recent work done by Shaffer and Woodyatt, and drew attention to its bearing in the construction of diabetic diets. The science of dietetics was not only of interest to the physician, but was also of importance to the surgeon. Much could be done by dieting to put a patient into the best state for operation, and careful attention after surgical assistance would give the invalid the best chance of permanent recovery in the case of many gastric conditions.

Referring to the question of dieting in hospital practice, Dr. Lyon described what had been done by the institution in nearly all large American hospitals of a special class of officials known as dietitians. The position and duties of these people varied, but they were responsible for the preparation of the food, acting on the prescription of the physician in charge of the case, and by this means an unlimited number of patients requiring special diets could be handled without adding to the work of the ward staff. Another important duty of this official was to instruct those patients who required it in the best methods of constructing, preparing, and arranging their diets. From his experience in the diabetic outpatient clinic of the Edinburgh Royal Infirmary, Dr. Lyon was convinced that the exact dieting required in this disease could be satisfactorily and readily carried out in general practice even by uneducated persons.

Dr. Claude Ker said that from his experience of certain febrile conditions, he was tempted to ask if diet in these cases had any beneficial effect at all. Typhoid patients seemed to do equally well on a full diet, on a light diet, or even on practically no diet. In this connection it may be recalled that in this country, and probably in America, the custom has been to feed typhoid fever patients on milk. To give meat would have been regarded almost as a criminal act, which was certain to be followed by disastrous results. The late Dr. Frederick Smith, physician to the London Hospital, was the first here to break through this routine, and in place of the disasters predicted figures showed that his methods of dieting were better than those who relied on milk alone. Dr. Ker said that he was interested to hear more of the rôle of the dietitian, and now that such an office had been established in the Edinburgh Royal Infirmary he felt sure it would not be long before a special diet kitchen was built, which would be of great help in handling those patients who required special care.

MEDICAL WOMEN'S INTERNATIONAL ASSOCIATION

This association will hold a conference in London from July 14th to 19th. The association was inaugurated in New York in 1919 and met in Geneva in 1922, when the constitution was drawn up. It is expected that some twenty-four nations will be represented in London in July, which will be the first meeting to be held under the fully constituted representative council. There will be business meetings,

and a discussion of maternal morbidity, its causes and prevention, and a full and varied program of entertainments and expeditions has been arranged. The honorary secretary of the Hospitality Committee is Dr. Kathleen F. Lander.

CONFERENCE ON INFANT WELFARE

The Third English-Speaking Conference on Infant Welfare will be held at Caxton Hall, Westminster, on July 1st to 4th, under the auspices of the National Association for the Prevention of Infant Mortality and the National Baby Week Council.

ART EXHIBITION BY MEDICAL MEN

This exhibition was held in the building of the Royal Society of Medicine, London, from May 26th to June 14th, and was remarkably good. There were about 220 paintings, etchings, water colors, photographs. Among the exhibitors were Sir Rickman Godlee, Sir William Lister, Sir Charles Tomes, Sir Squire Sprigge, Sir Harry Baldwin, Dr. Leonard Hill, Dr. A. F. Hurst, Mr. J. Hutchison, Dr. Claude Rivière, and the well known American authority on nervous diseases, Dr. Starr.

LETTER FROM PARIS

PARIS, *May 25, 1924*

(*From our own correspondent*)

SEX PROPORTION

New light was thrown on the mysterious influences which decide the sex of living things, by Dr. F. A. Crew in a lecture at the Royal Institution. Sex ratio or the proportion of males to females at birth should be as one to one, he said, but, though fairly constant and not far from equality, it is distinctly variable and is rarely in the proportion of one to one. The proportion varies with the season of the year, the season of the highest birthrate being that of the lowest proportion of males. There is a continuous drop in the sex ratio as the number of offspring increases. In the case of a fowl, the first batch of eggs yields a high proportion of males, the later eggs yielding a low proportion. In the case of the rabbit, the proportion of males is higher among the female's elder or firstborn offspring. There is no support for the theories that sex ratio is affected by differences in the age or vigor of the parents.

HIGH BLOOD PRESSURE

Blood pressure caused by the pumping of the blood through the arteries is, of course, essential to life. Danger arises when the pressure becomes too great and hardened arteries give way. Excessive tension of the arteries is a symptom rather than a disease. It is a symptom that appears after certain changes in the structure and in the functions of the body have occurred, some of which we have been able to trace, though others still remain unknown. The high blood pressure is needed for the welfare of the body as changed. It is these changes, whatever they may be, that must be sought out and, where possible, removed.

Regular exercise, taken in fresh air, is essential to health and is one of the most important of the measures for the prevention of the processes that lead to high blood pressure. Habitually heavy meals, whether served at noon or in the evening, are among the important factors concerned in the origin of the arterial hypertension of later life.

The poisons retained in the system and circulating in the blood as a result of impaired kidney function are a potent source of damage to the arterial walls. Apoplexy, serious as it is, does not occur as frequently as many people imagine. Caffeine, nicotine and alcohol have been accused of being potent causes of arteriosclerosis but recent researches do not seem to support the accusation so far as moderate use is concerned.

Cultivate tranquillity, avoidance of bad colds, sore throats, and tonsillitis, which are capable of doing great harm to the heart. Take ample recreation and holidays, and let meals be unhurried. Sleep in the open air. The modern house that is not well supplied with sleeping porches is incomplete. Most important of all, the cares and anxieties of the day should be shed by the mind at bedtime just as thoroughly as the clothing is removed from the body.

LECTURES FOR FOREIGN STUDENTS

The Inter-University Institute of the University of Rome is arranging a course of lectures for foreigners. The subjects will be the papacy in the first centuries of the Middle Ages, the history of medieval and modern art, Italian literature, the history of music, the Sistine Chapel, the Palazzo Venezia and the Borghese Gallery, with an excursion to Orvieto and a lecture in the chapel of the Signorelli; the churches of San Clemente, Santa Maria in Aquiro and Santa Cecilia in Trastevere, the Lateran Museum, with visits. Students who join these courses have free access during the period to the museums and galleries of Rome. Information may be had from the secretary of the Inter-University Institute, Signora Maria Antoinetta Scotti, at the Palazzo Venezia.

THE AMERICAN MEDICAL SOCIETY OF PARIS

This society held a successful meeting recently at the American University Union, under the presidency of Dr. Edmund L. Gros. Physicians, both from Paris and various parts of the United States, listened with attention to the interesting address of Dr. P. Armand-Delille, physician to the Hôpital Debrousse and the American Hospital of Paris, who described the modern methods of diagnosis and treatment of pulmonary and bone tuberculosis. The outdoor treatment in pure air and sunshine still gives the best results, he said, and Dr. Armand-Delille sounded a note of warning against socalled specific serums, which have never demonstrated their efficiency and often lead to neglect of the climatic treatment which alone can effect a cure.

He showed the great mortality of poor children whose parents were tuberculous, the contagion often taking place through the eyes. Prof. Léon Bernard and Prof. Bezançon have shown that sixty per cent. of these young children die of tuberculosis if left in their homes in contact with their parents, while if these same children are sent to the country the disease develops in less than three per cent. With regard to diagnosis, the x ray still remains the best method. Blood reactions are being

studied by Besredka of the Pasteur Institute, but so far, have given few results because almost every inhabitant of a big city has at one time or another had some tuberculous lesion which nature has cured without treatment, but which suffices to produce blood reaction (complement fixation) similar to those occurring in progressive tuberculosis. Dr. Armand-Delille reported wonderful results with children in whom unilateral tuberculosis existed, by artificial pneumothorax. These children run about and play, one lung being quite sufficient for their respiratory needs. This treatment must be kept up for three years to obtain a cure.

Dr. A. Bruno then spoke of the work of the Rockefeller Commission in France, and showed that there were now about 421 antituberculosis dispensaries in France, as against 600 in the United States. These have all been developed since the commission came to France. The weak side of the treatment now consists in the great lack of sanatoria in France for poor people. There are about nine thousand beds in all in France, where about sixty thousand are needed, and only 729 beds for middle class or paying patients. Films of pulmonary lesions and the destruction of bacteria by phagocytes were shown.

NOTED AMERICANS IN PARIS

Dr. Eugène Lyman Fisk, medical director of the Life Extension Institute of New York, has arrived in Paris on a tour of France, England and Italy. It is his purpose to confer with leading health authorities with regard to the development in Europe of the plan for extending human life by means of periodical health examinations and the practical and direct application of the laws of individual hygiene.

Surgeon General Hugh S. Cumming, U. S. Public Health Service, attended a meeting of the League of Nations Health Committee held in Paris recently. Before coming here he had conferred with the Ministry of Health in London regarding quarantine arrangements at the five leading British ports. After the conclusion of his Paris conferences, he will go to Rome as delegate to the International Conference on Emigration.

Dr. Robert Kelly, director of the American Association of Colleges, spoke to some two hundred students and professors at the Sorbonne on the American educational system, defining particularly the modus operandi of the liberal and vocational schools and colleges. "The tendency in the United States," said Dr. Kelly, "is for the high school to throw off the domination of the college and university. The colleges, as a result, have followed in the footsteps of the State universities, and have lowered their entrance requirements. A discovery made by surveys of educational institutions by the Carnegie Foundation disclosed the fact that while colleges allow an increasing flexibility of subjects, the students still concentrate on those subjects that have always been considered fundamental."

Mrs. Josephine Dascom-Bacon, the short story writer, will be the guest of honor at the monthly club luncheon of the American Women's Club. Mrs. Bacon will read some of her new and unpublished stories.

Miss Hogg, art lecturer, will speak for the benefit of the American Women's Club. The subject will be "The Works of Rodin." The entire proceeds of the lecture will be donated to the New Club House Fund.

Dr. H. P. Judson, president emeritus of the University of Chicago, chairman of the Committee of the American University Union, and one of the original trustees of the Rockefeller Foundation, has arrived in Paris, where he will remain until late in June, before visiting Norway, Sweden, and Denmark in behalf of the American-Scandinavian Foundation. Dr. Judson is president of the Chicago branch. An extensive interchange of American and Scandinavian students is being planned. The American-Scandinavian Foundation has lately received large funds, Dr. Judson said, among which was a bequest of half a millon dollars left by a Scandinavian. Dr. Judson said that the American University Union is now organized on a firm basis in America, thanks to the Laura Spellman Rockefeller Memorial, which gives to the Union $25,000 a year for five years.

A major of the United States Army is one of the members of a military mission which is visiting the battlefields of Verdun and Metz with a view to investigating the lessons in strategy to be drawn from the fighting in this region during the war. The mission includes ten French generals and several colonels, as well as high grade officers from the Serbian and Greek armies.

VIENNA LETTER

(From our own correspondent)

Vienna, *January 12, 1924*

IMPROVED CONDITIONS IN AUSTRIA

The change of conditions in Austria, socially, industrially, and in science and art, which is nothing short of marvelous, has set in with the stabilization of the currency, brought about by the loan the League of Nations secured for Austria in September, 1922. This stabilization of the money system has resurrected a people which for years bravely faced utter misery almost without hope. The revival of interest in medical progress can not be understood unless viewed from the viewpoint of economic restoration. The financial restoration is well illustrated by the report which Dr. Zimmerman, the controller of finances appointed by the League of Nations for Austria, submitted in Geneva in September, 1923. The currency of Austria has become the most steady money in Europe, returning Vienna to its former place as an international trading centre. The harnessing of waterpower in the Austrian Alps, managed mostly with the help of Austrian money, will become a great asset in Austria's trade balance, as it will make unnecessary for Austria to pay those tremendous sums for coal importations.

The saving policy cut deep into the existence of Vienna's scientific and medical institutions. Professor Menghin, for instance, complains of the miserable conditions in the prehistoric department of the Vienna University; the monthly salary of a younger professor is about three million kronen (forty-five dollars), as much as a washerwoman

vill earn. The institution, which was founded by Hoernes in 1899 and has since become internationally famous, has been allotted a room in the basement of the university, underneath a row of waterclosets; the latter often causing an intolerable stench by leaking through the ceiling; the ventilation being unsatisfactory, Professor Menghin finally succeeded in getting a room outside the university. His institution gets a subsidy of two hundred thousand kronen a year from the government—three dollars. One may easily understand such a state of affairs if one knows that the government spent five hundred billion kronen for the army last year, but only half of this amount, two hundred fifty-eight billion, for *all* of its educational institutions. This saving policy of the government, commendable though it be, has wrought havoc also with the once famous anatomic institution of Vienna. The dead bodies of poor people, not claimed for burial by relatives, socalled flunked bodies, used to be transported from the hospitals to the anatomic institution by the city's undertaking establishment. The minister for social administration broke the contracts with the city and entered into a contract with another firm, because the latter offered to bury the poor people's corpses or transfer them to the anatomic institution without any charge, beside paying the government a yearly bonus of seventy million kronen! This latter firm tried to squeeze out of the relations of such flunked corpses at least a part of the burial expenses by telling them they would not deliver the corpses to the anatomic institution if the relations paid them some money. And the consequence of this poor saving policy is this: In the year 1921-1922 the anatomic institution obtained seventy-eight bodies. In the year 1922-23 it received only twenty-two bodies. This year it received to date only one body. As there are about one thousand students who wish to do dissecting, only the native students can be admitted to the work. The foreigners, who by their large tuition fees make the running of the institution possible, are excluded from the work.

Owing to the saving policy of the government, the chemical departments of the university came near closing their doors. The chamber of commerce decided to bring help; after convincing the prominent industrialists and merchants of the absolute necessity of having fully educated young chemists in their employ, it succeeded in collecting one hundred million kronen, which, in addition to the supply of chemicals, glass and china ware and other utensils, free of charge, was sufficient to save the situation.

A man by the name of Bosel, now president of one of the strongest banks in Vienna, offered the university any amount of money needed to carry on its scientific research.

In the course of last year there were brought before the juvenile court of Vienna 127 children, aged from ten to twelve years, 570 aged thirteen to fourteen years, 1,107 aged fifteen to sixteen, and 826 aged seventeen to eighteen. They were accused mainly of theft, but many also of burglary, fraud, arson, rape and—the girls—of prostitution. The stories of Victor Hugo are mere fairy tales compared to the wretched stories heard in this court. All these youngsters have been brought up and fed on war and its virtues. In Vienna, Munich, Budapest, Berlin—in every place of the defeated world—these youngsters are collecting daggers, poisons, bombs.

ABORTION

Another sign of reawakened public conscience is the present attitude of the courts toward commercialized abortion. The State prosecutor maintained, in an edict addressed to the medical organization, that it is the duty of every physician to bring cases of criminal abortion, even if only suspected by him, to the notice of the prosecutor's office or run the risk of being prosecuted himself. This edict created some excitement among the physicians, who refused to do detective work for the public prosecutor. In November last, several physicians were called before the court, accused of criminal abortion. Two of them, quite prominent practitioners, were found guilty and received a sentence of three months in jail. Thereupon the medical society of Vienna called a special meeting and passed a resolution addressed to the Minister of Justice in which it petitioned that the court should employ in the future as medical experts on the stand not pathologists—as heretofore—but exclusively physicians with clinical experience, conversant with the responsibilities of a practitioner at the bedside; the pathologist might do for autopsies but he is not supposed to know much about the clinical requirements of the physicians at the bedside of living patients. Another prominent physician wrote an article in the daily press, elaborating on the modern viewpoint on abortion, stating that the indications for legal interruption of pregnancy should not be merely of a medical nature, but also of a social and economic nature; that the present law concerning those indications is too narrowly drawn for modern requirements. This present attitude of the Medical Society of Vienna, if compared with the personal attacks, directed against me, for having mentioned commercialized abortion in my last report to the MEDICAL JOURNAL AND RECORD (April, May, June 1923), seems rather paradoxical.

MEDICAL OPTIMISM

However, there is no doubt, that the members of the medical profession whom the war has not rendered hopelessly decadent, are trying their hardest to get on their feet again. Witness thereof are the two lectures delivered by that jovial, honest straightforward Dutch Professor Wenckebach. He spoke, after his return from the United States, on "What We Can Learn from America," and his observations were certainly to the point and much appreciated by the crowded audience. Among other things "we should learn to do away with titles," he said. I am the native of a country where no titles exist and no heed is paid to formalities. It would be a glorious deed for the Austrian physicians if they would follow the example set by their American colleagues and do away with that abominable councilor business. The Medical Organization, two months before this lecture was delivered, had passed a resolution asking the government to stop the granting of such titles as Medical Councilor, because it was not in keeping with a democratic mentality and besides, was misleading the public, which looks upon such titles as a sign of better medical qualification, while, in fact, they were merely the sign of a certain influence the bearers had with the granting authorities.

Book Reviews

CANCER

Cancer of the Breast. With a Study of Two Hundred and Fifty Cases in Private Practice. By L. Duncan Bulkley, M.D. With Forty Illustrations. Philadelphia: F. A. Davis Company, 1924. Pp. x-336.

For forty years the author has studied cancer from medical rather than surgical lines and he says he has obtained much better results than are obtainable with other plans of treatment. The theory is advanced that cancer of the breast is a general disease (carcinosis) with local manifestations in the breast, "with exaggerated and distorted cells originally normal, which, having mutinied and lost their nervous control, and having thrown off their physiological allegiance, no longer perform their former secreting function, but having still the power of growth, multiply and form the useless and ultimately harmful masses" called cancer. The perverted action is attributed to a perverted or erroneous condition of the blood from which the cells receive their nutrition, the actual mutinous action being excited by an external agent as a local injury, surgical interference, or a pus forming microbe, or possibly from an internal irritating cause, as uric acid.

In the chapters on anatomy and physiology of the breast, lymphatic permeation, carcinoma and Paget's disease, sarcoma of the breast, and on diagnosis and prognosis, nothing new is presented, but when we come to the chapters on the medical aspects and the treatment of breast cancer, the views expressed are held by few, if any, except the author. However, in view of the fact that cancer appears to be constantly on the increase in spite of all forms of treatment, these statements deserve at least consideration, no matter how radical in thought or conservative in action they may appear to be. In substantiation of his theory, eminent authorities of the past century are cited, but the citations refer only to theories and possibilities and not to actual facts or incontrovertible data; they are merely opinions and can be classed only as such. They need proof.

The causes of the disturbed and perverted metabolism are studied under the following heads: food and mode of life, faulty metabolism, imperfect blood stream, erroneous body elimination and nervous disturbances, all of which are admittedly much too prominent today. However, no single cause can be made responsible for the occurrence of cancer, nor is there a single remedy to cure it. The author says that "the most careful medical treatment accomplishes far more than the methods of treatment in vogue of late years," especially surgery. The latter is said to be directed to the local manifestation and not to the disease itself. In the treatment of breast cancer, surgery is discredited and the favorable reports on it are attributed to faulty diagnosis. Irradiation (x ray and radium) therapy is also discredited. Caustics are favored because they prevent lymphatic permeation. Chemical removal, as practised by Strobel, is endorsed, but only in association with a thorough and intensive medical measure. Biotherapy, with the exception of Coley's fluid and proteotherapy in carcinoma, is said to be ineffective. Great stress is laid upon dietotherapy, which should be persisted in permanently to avoid recurrences. An absolutely vegetarian diet is recommended. Fruits, especially raw, are now believed to be beneficial. Hygienic living, the promotion of elimination by the emunctories and the correction of faulty habits or conditions of life are most important elements in the treatment. Opiates and most sedatives are blamed for increasing the carcinosis by interfering with the glandular structures and thereby vitiating the blood stream. The medical treatment should include potassium salts, phosphorus and iron. Aspirin is recommended for the relief of pain. The local treatment includes ichthyol, diachylon ointment and calamine and zinc, with or without morphine (sic!), phenol, hydrogen peroxide, potassium permanganate and cocaine (for pain).

Sixty-one case histories are reported and give the impression that the author has failed to prove that medical treatment is superior to the surgical treatment of today. In many cases the treatment outlined has failed to prevent the advance of the cancer and to allay the sufferings of the patient. The treatment recommended will aid in cancer as well as in any other condition or disease, but there is nothing specific about it. On the whole, the book is disappointing because it fails to prove its point. It is full of theories, but no effort toward proof is made. Surely forty years of experience should have brought forth something more definite! If there is a germ of truth in the theory advanced, the author has not succeeded in bringing it out.

CARCINOMA OF THE UTERUS

Die Röntgenbehandlung des Uteruskarzinoms. Von Dr. Med. et Phil. Hermann Wintz. Mit 50 Lichtdrucktafeln. Leipzig: Verlag von Georg Thieme, 1924.

The Seitz and Wintz technic of deep x ray therapy for carcinoma of the uterus, as it is used at the Erlangen University Gynecological Clinic, is described. Only the fundamental principles are mentioned but the minor details must be varied to suit the individual case. Although the proper apparatus is an important element in the successful carrying out of the technic, nevertheless the medical attention and the proper dose are most important elements. The basic principle of this form of treatment is the fact that a minimum of ninety per cent. and a maximum of one hundred and ten per cent. of the skin unit dose is the proper dose for the entire carcinomatous area. Three phases are distinguished in the reaction: 1, the destruction of the viability of the carcinoma cell; 2, the degeneration of the carcinoma cell and elimination of the degeneration products from the body; 3, the growth of healthy body tissue at the site of the neoplasm. The single maximum dose is indicated in ovarian irradiation, but it is a necessity in carcinoma of the uterus. The duration of the maximum dose should be as short as possible. The preradiation and postradiation treatments must take into consideration the effect of the treatment upon the entire organism and the resulting local injury must be as slight as possible. The

preradiation treatment is given as long as the initial reaction, which usually lasts fourteen days, continues. The general practitioner or the attending surgeon is given detailed instructions in regard to the postradiation treatment. The preparatory treatment is described in detail, as are also those of the irradiation treatment. The copper plating process, which is an essential part of the treatment and consists of the elements of electrolysis and cataphoresis, is accurately described. The aids used in the proper focusing of the rays and the postradiation treatment are also discussed. There are fifty photogravures, which illustrate the manner of irradiating the primary tumor and the parametria. The technic varies in women with normal deposits of fat and moderately broad pelves from that used in very obese women and very broad pelves. In each case the anterior and posterior fields of ray concentration are shown and marked. The manner of irradiating the parametria in one or two stages are also shown. The Chaoul-Langer technic of focusing is illustrated. There is also a plate showing a false method of focusing and one showing an x ray burn due partly to adhesive plaster.

The book is an excellent treatise on the Seitz-Wintz method of deep x ray therapy.

THERAPEUTIC VALUE OF SUNLIGHT

Sunlight and Health. By C. W. Saleeby, M.D., Ch.B., F.Z.S., F.R.S.E. With an introduction by Sir William M. Bayliss. New York and London: G. P. Putnam's Sons, 1924. Pp. 198.

The discoveries of the last few years and the recognition that sunlight in itself is a powerful health giving and restorative agent, have abundantly justified Dr. Saleeby's persistent advocacy of the therapeutic use of sunlight. This book gives an outline of the whole interesting field of the phenomena of this subject. We know already that the most striking effects of light have shown themselves in the cure of such diseases as rickets and tuberculosis, and that it also prevents the development of these under circumstances when otherwise they would assuredly show themselves. Hence, we see the justification of the efforts being made to prevent pollution of the atmosphere by smoke, in which efforts Dr. Saleeby has taken part energetically. There is still much to be learned of the way in which light acts, and as to the particular rays of the spectrum which are active in different cases, and one of the services of this book is to indicate these gaps in our knowledge, and to incite research with a view to filling them.

Dr. Saleeby states that his book is designed for the medical profession and the public, to commend sunlight as the primary and hitherto most neglected means of health and medicine against disease. He attributes to himself no new discovery; for Hippocrates himself, the Father of Medicine, advocated the use of sunlight as a cure, and built a sanatorium where patients might avail themselves of such a treatment. The ideal combination, Dr. Saleeby believes, is cold and sunlight, and he states to confirm this opinion that the Canadians, who enjoy these conditions, thrive under them and are one of the healthiest peoples in the world. He urges the abolition of coal fires and the building of houses which will receive a maximum amount of sunlight.

DIABETES

Diabetes. A Handbook for Physicians and Their Patients. By Philip Horowitz, M.D. With Thirty-Four Text Illustrations and Two Colored Plates. Second Edition Revised and Enlarged. New York: Paul B. Hoeber, Inc., 1924. Pp. xii-219.

The aim of this second edition is the same as that of the first—cooperation between the doctor and patient and also to incorporate the latest methods of insulin therapy and the calculation of maintenance diets. The insulin treatment of severe and juvenile cases is thoroughly discussed. The proper maintenance diets are worked out and seventeen new formulæ and recipes are added. The Van Slyke test for the carbon dioxide combining power of the plasma and the Folin and Wu sugar test are essential when insulin is being used. Cases showing various phases of diabetes and complications and their methods of treatment are cited. An intimate knowledge of dietetics is necessary to balance accurately the diet and insulin. The author does not recommend insulin therapy in mild cases because the ordinary dietetic treatment seems to be able to restore the pancreas to function after a mere reduction of the sugar in the urine and the blood.

After going into the general considerations of diabetes, mild, moderately severe and severe cases of diabetes are discussed. Acidosis and coma, the complications, hypoglycemia and the value of hygiene and exercise are then taken up. A separate chapter is devoted to menus, recipes and tables of food values, which should be very helpful. The following chemical tests are described in minute detail: the Benedict qualitative and quantitative tests for glucose in the urine, a rapid test for estimating the sugar in the urine, the sodium nitroprussic test for acetone, the ferric chloride test for diacetic acid, the Folin test for blood sugar, the Van Slyke test for plasma bicarbonate and the Epstein microcolorometric test for blood sugar. The appendix gives a short history of diabetes. The purpose of this little book is well carried out.

AUTOSUGGESTION

Selfhealing by Autosuggestion. By A. Dolonne. New York: E. P. Dutton and Company, 1923. Pp. v, 110.

Dolonne believes that he has delivered the subject of autosuggestion from its mysterious character and established it upon a scientific basis. He has pointed out, it is true, that its apparent mystery is to be found explained within the mind of the individual himself, in activities taking place beneath consciousness. He has given us, however, no scientific revelation as to how such activities take place nor as to their nature. By his mere reiteration of words in terms of his own enthusiasm he has only substituted one mystery for another. We agree with him that that which takes place in the mental life influences bodily health as it forms the basis of mental health or illness. But instead of a lucid analysis of such mental activity he is content to deliver himself and his reader over to the spell of sounding phrases. He is an evident victim of the autosuggestion which he conceives and upholds. Repetition in a certain hyperbolic enthusiasm of thought and speech may arouse the attention of many readers to make them devoted adherents of this sys-

tem of healing. For affective cravings are gratified in a variety of ways. An intellectually active mind, on the other hand, cannot be satisfied with mere statements such as "Autoeducation will make our children intelligent and energetic men—noble, loyal, proud and happy," and other such effusions of an exalted optimism. Nor is it easy to accept autosuggestion as here set forth as a "moral serum which plays a decisive part in all diseases." This author does not believe in analysis, he says, but intelligence demands to know something of the content of the idea for which Dolonne claims the decisive power over the mind. It requires also a more correct science of psychology and of neurology than he has at his disposal. What must be said of a statement like this? "If the same nervous centre is applied to every day, if every day its activity is stimulated by carefully practised autosuggestion, from force of habit this nervous centre develops and grows and its nerve cells multiply. Where formerly there was only one nerve cell, there will now be ten or twenty, discharging a function ten or twenty times as great."

CLINICS

International Clinics. Edited by Henry W. Cattell, A.M., M.D. Volume IV. Thirty-third Series, 1923. Philadelphia and London: J. B. Lippincott Company.

Twenty-six contributors take part in the current volume of this popular publication, the outstanding feature of which is a symposium on gastrointestinal ulcers, by M. J. Stewart, of Leeds, England, Samuel Danon, of Geneva, Switzerland, Seale Harris, of Birmingham, Alabama, and T. A. Groover, A. C. Christie and E. A. Merritt, of Washington, D. C. Another striking feature of this volume is the Alvarenga Prize Essay of the College of Physicians of Philadelphia for the year, 1923, entitled "A Treatise on Echinococcus Disease," by E. B. Heller, of Kansas City. This essay represents an effort on the part of its author to assemble all of the important facts regarding echinococcus disease into one monograph. The lay public will be interested to learn that the solution of the problem of prevention of this disease is to be found in the segregation of dogs and cats. The author illustrates the pathology of the disease in a number of the organs of the body by means of photographs of specimens from his own case, an ape, Cynocephalus porcarius.

Judson Daland, of Philadelphia, has an interesting article on "Altitude Sickness the Result of Hemoglobin Deficiency," and D. N. Eisendrath, of Chicago, presents a useful paper on "Tuberculosis of the Kidney." All the papers are of excellent quality and the typography and illustrations all that could be wished for.

* * *

The Surgical Clinics of North America. February, 1924, Volume 4, Number 1. Philadelphia Number. Philadelphia and London: W. B. Saunders Company, 1924.

A large part of this volume is devoted to fifteen contributions by the bronchoscopic clinic of Chevalier Jackson. These range from a clinic on pyloroscopy, by Dr. Jackson, to Shallow's clinic on gastrostomy, in which a new technic is demonstrated. Newcomet's clinic on the use of radium in cancer of the larynx is exceptionally interesting, as is Lukens' clinic on pulmonary abscess following tonsillectomy.

Deaver and Reimann contribute an instructive clinic on the essentials of surgical diagnosis which deserves most careful attention. Behrend's clinic on the symptoms and pathology of acute intestinal obstruction is most timely and instructive. Additional clinics combine to make this number one of the most attractive of the series. The usual excellence in typography and illustrations is maintained.

* * *

The Surgical Clinics of North America. (Mayo Clinic Number)—April, 1924, Volume 4, Number 2. Philadelphia and London: W. B. Saunders Company, 1924.

Thirty-three members of the Mayo staff contribute to this volume. The clinics are of the usually high order, splendidly and freely illustrated. Bumpus presents an interesting clinic of a case of complete urinary retention complicated by extensive destruction of renal function, the result of prostatic hypertrophy. Five days were consumed in emptying the bladder in this patient, an evidence of the great care exerted to maintain a continuous but diminishing blood pressure and thereby avoiding serious risk of untoward symptoms or death.

Scholl and Judd have an instructive clinic on hydronephrosis and pyonephrosis, Buie a clinic on carcinoma of the rectum, and Vinson an excellent clinic on obstructions of the esophagus and cardia. The volume contains 179 illustrations.

CRISIS

The Book of Blanche. By Dorothy Richardson. Boston: Little, Brown & Co., 1924. Pp. 358.

Not many writers have the gift of seeing and seizing *the* moment of the lives they portray. In Blanche Walska's history there is so much that might have stood for the revolving pivot; her mother's tragedy; her childhood; her miraculous moment of triumph. But the *Book of Blanche* opens at the one page of Eugene Sevier. And from that page lead a thousand ramifications. For Sevier has a book of his own. And as Blanche's draws to a close, Sevier's begins. There will be living, heartrending year after year. There will be work to deaden, inexorable progress. And there will always be the few pages of Blanche to read anew and to keep him going.

Sevier is the house surgeon at the hospital to which Blanche Walska is brought for a cancer operation. She is the illegitimate child of a world famed violinist. Her whole being has yearned towards one goal—a career. And she has worked for it tirelessly until fate stepped in. The burly Southern doctor and this flowerlike foreign girl are swept into one of those vibrating vortices of emotion for which only the violin lover can attempt the simile. Blanche is at the hospital for a few brief weeks. Like two moths, they flutter about the flame of their love. There is no escape. Blanche has her chance to a certain extent. She triumphs for a night on the concert stage. Perhaps life could hold no deeper joy than her love and her success. The next morning brings the end. And Sevier is left with the memory, the pain,—yet knowing desperately that it could not have been otherwise.

Miss Richardson has a true gift. Her focus on her picture is perfect. There is music in her writing, harmonies or words and thoughts that bring as full contentment as color or sound harmonies. She is a creator, and has shaped flesh and blood.

Medicoliterary Notes.

The Show-Off, a comedy by George Kelly, is a fine piece of human psychology both in conception and interpretation. Louis John Bartels has the title part.

* * * *

A King's Morning Talks to His Brother's Son is the title of a curious old manuscript recently brought to light among other of the German official archives. It is supposed to have been written by Frederick the Great for the benefit of his nephew and its style shows the author's characteristic cynicism and irony. His definition of politics is worth quoting. "As soon as men came to the conclusion that it was sinful and base to deceive their fellowmen, they began to hunt about diligently to find a word that would condone such actions with a pleasing name. They hit upon the word *politics*."

* * * *

The publication of a new periodical has recently been announced—the *Journal of Scientific Instruments*. It will be issued by the British Institute of Physical Science in connection with the International Physical Laboratory. The editor is Dr. John S. Anderson .

* * * *

That prolific writer, William S. Walsh, is the author of another recently published work entitled *The Mastery of Fear*. The book is an interesting contribution to the psychology of neurotic and neurasthenic as well as normal fears.

* * * *

A new publication of Longmans, Green & Co. is *Crime and Insanity* by Dr. W. C. Sullivan, medical superintendent of Broadmoor Criminal Lunatic Asylum. His point of view is that of the criminal as a social problem.

* * * *

The *Saturday Review of Literature* is a new independent weekly under the editorship of Henry Seidel Canby, William Rose Benet, and Amy Loveman, all formerly of the New York *Evening Post*. The same group founded in 1920 the Post's weekly *Literary Review*.

* * * *

Toronto has a new magazine entitled *Hospital Buying*. Its editors describe it as "a magazine for hospital executives." It consists for the most part of news and information about Canadian hospitals.

* * * *

Arthur Rackham, the well known illustrator of fairy tales, is making illustrations for Christopher Morley's *Where the Blue Begins*. The pictures of the dog people in the book are said to include a number of clever caricatures of familiar human types.

* * * *

That the newspaper plays a vital rôle everywhere under all conditions is proved by the demand of the inmates of the Kalaupapa leper settlement on the island of Molokai, Hawaiian Islands, for permission to run a newspaper for themselves which would be financed by a few wealthy residents of the settlement.—*Nation's Health*.

* * * *

Irwin Erdman has an entertaining article in the *Century* for June on *We Superstitious Moderns*, in which he advances the theory that the people of today believe as firmly in their "medicine men" and socalled miracle workers as did any of the ancients—and one of the greatest of these modern curealls is the *libido!*

* * * *

I look my age, and I am my age. It is the other people who look older than they are. What can you expect from people who eat corpses and drink spirits?—*Bernard Shaw* in *Harpers*.

* * * *

Chili has an ambulance under government operation that is run on the railroad track. It is constructed like the ordinary public autoambulance, differing only in its ability to run on a track.

* * * *

Remnants of the original tablets of the Ten Commandments, it is believed, have been deciphered by Professor Grimme of the University of Münster. "I was taken out of the Nilus by an Egyptian queen" is written in Hebrew so old that it is almost a forgotten tongue at the top of one of the tablets. They contain also the names of Joseph, Menassa and Moses. The tablets were discovered on a plateau of the Peninsula of Sinai by Flinders Petrie.

* * * *

New York State has more playgrounds than any other State in the Union, according to figures recently compiled and published by the Playgrounds and Recreation Association of America. New York has 858, Massachusetts 706, and Pennsylvania 687.

* * * *

One of the new publications announced by Putnam is the *Life and Letters* of Mary Putnam Jacobi, edited by Ruth Putnam. Mary Putnam Jacobi studied at the École de Médecine in Paris more than fifty years ago. After completing the course there with honors, she came to New York City and devoted the rest of her life to work among the poor. The book should be of interest to all interested in the long fight made by women to gain recognition, not only in the field of medicine, but in that of professional life as a whole.

* * * *

Hell-Bent fer Heaven, by Hatcher Hughes, the play that received the Pulitzer prize for the best play of 1924 dealing with some phase of American life, has been published in book form by Harper Brothers.

* * * *

In a recent number of the *Bookman*, Mary Austin discusses the subject of *Genius and Temperament* in the fourth article of her series on *Making the Most of Your Genius*.

* * * *

The Paris press has announced the finding of Voltaire's heart in a small casket which was placed many years ago for safe keeping in the National Library of Paris. In a little used room of the building Roland Marcel, new curator of the library, noticed on his first round of inspection a plaster bust of Voltaire beside which was a wooden pedestal with the inscription "Voltaire's heart." M. Marcel found the button of a secret trap, which, when pressed, disclosed a small compartment containing the little casket with the heart. No record had been kept of its hiding place so it had been entirely forgotten.

* * * *

The results of some investigations on the actual practical usefulness of tests and test methods in business, and the possibilities of their future development, are discussed in a recent publication of the University of Chicago Press entitled *Psychological Tests in Business*. The authors are A. W. Kornhauser and F. A. Kingsbury of the department of psychology of the University of Chicago.

* * * *

The Life and Letters of Emily Dickinson, by her niece, Martha Dickinson Bianchi, recently published by Houghton Mifflin Company, is interesting material for psychoanalysis. Miss Dickinson, who was born in 1850, lived almost as a recluse for the greater part of her life at Amherst, Mass., her birthplace, yet her poems show a keen understanding of life and knowledge of human nature.

* * * *

The New York Association for Improving the Condition of the Poor has recently issued two interesting and valuable little pamphlets written by the director of the department of social welfare, John C. Gebhart. These are entitled respectively *The Health of the Neighborhood*, a survey of six years of public health work in the Mulberry district of New York City; and *Tuberculosis, a Family Problem*, an analysis of ten years' work at the association's home hospital, demonstrating the effectiveness of properly directed treatment of tuberculosis in the home as a means of supplementing existing sanatorium facilities.

* * *

A graduate nurse who is a fullblooded Indian has been assigned by the State Department of Health and Welfare of Nebraska to maternity work among the Indian women of the State reservation. This new project has been undertaken under the provisions of the Federal Maternity and Infancy Act.

* * * *

Amazona is the name of a new coffee substitute found in Venezuela and said to have all the properties of coffee except the caffein. It is the fruit of a weed growing in abundance and used to make a beverage by the Meta Indians after they have toasted it.

Abstracts from Current Literature

MALIGNANT GROWTHS

Lymph Glands in Carcinoma of Small Intestines.—W. McK. Craig (*Surgery, Gynecology, and Obstetrics,* April, 1924) presents tabulated reports on series of cases and abstracts thereof, reaching the following conclusions:

Although resection of the bowel with all associated glands is the operation of choice and produces the best postoperative results, yet anastomosis around the lesion results in a high percentage of postoperative longevity.

In considering the three anatomical divisions of the small intestine with regard to postoperative progress, in cases of carcinoma, it was found that the prognosis is most favorable in cases in which the lesion is in the jejunum. The hospital mortality was the least, and the percentage of longevity greatest in these cases. Lesions of the duodenum are not only difficult to eradicate, but by the time they become manifest, they are so advanced that ablation is impossible. There seems to be a high hospital mortality from lesions of the ileum. The only patient living any length of time had a malignant papilloma which was extirpated, and there was no glandular involvement. Carcinoma of the small intestine is the least common form of gastrointestinal malignancy. The majority of patients are between forty and sixty years of age. The most common site of primary malignant neoplasm in the patient's series was the jejunum which contained forty-six per cent, of the carcinomata.

The size of the growth in the small intestine cannot be relied on as an accurate index of the probable lymphatic involvement; neither can the history or duration of symptoms indicate the extent of metastasis. Metastatic involvement of the lymph glands can be definitely determined only by systematic microscopic study of all regional lymph nodes. The size of the lymph node or the number of palpable glands has been proved not to be an index to the amount of involvement. The microscopic study of the associated glands in this series has been of further diagnostic value in determining the type of malignancy, especially in the cases which were secondary to malignancy elsewhere in the body. Adenocarcinoma is present in all primary carcinomata of the small intestine, but the possibility of the growth being secondary must be kept in mind.

Malignancy of the small intestine may simulate the primary type, and on microscopic examination prove to be secondary, as is illustrated by the cases of melanoepithelioma and squamous cell epithelioma, as well as by ovarian and uterine malignancies. Therefore, it is only by systematic microscopic examination that it is possible to rule out local metastasis in cases of carcinoma of the small intestine. A further important object of microscopic study is the determination of the type of malignancy, which is an index as to the primary or secondary nature of the growth, and, as such, assists in the prognostication.

Permanent Cures Following Operations for Cancer.—Alexander Fraenkel (*Wiener klinische Wochenschrift,* January 31, 1924), recalls that there are two factors which interfere with permanent cures following operations of cancer, namely: 1. Perforation into the blood stream, which may occur very early in the course of the cancer, thereby producing matastases. 2. Lymph node metastasis, which is not controllable by the operation because it lies beyond the field of operation or because it may entail dangerous complications. These unfavorable occurrences do not, however, invariably take place. Most unexpectedly and very frequently there is a dissemination of cancer cells into the lesser pulmonary circulation, but only a small part of these disseminated cells produce metastatic tumors or break through the arterial walls into the perivascular lymph spaces. Most of them are either destroyed or encapsulated and made harmless in spite of their capacity for growth through the organization of their thrombotic covering. Some of them, naturally, permeate the surrounding connective tissue thrombus into the capillaries and pulmonary venules and thus give rise to the formation of secondary tumors in the region of the greater circulation. All this may go on without the lungs showing any macroscopic changes. The organism can, even though not in every case, but in a considerable number, become the master of the situation; where this fails the operative results are nil.

Carcinoma of the Duodenum. — D. M. Vickers (*Annals of Surgery,* February, 1924) sums up his study as follows:

Carcinoma of the duodenum is clinically unusual and is found in 0.033 to 0.09 per cent. of hospital autopsies. Carcinoma is most frequent in the second, descending or periampullary portion. Next in order of frequency is the first portion, and last is the third or juxtajejunal portion. There are no significant facts in its site, age, distribution, preceding symptomatology to suggest an etiology, other than those of neoplasms elsewhere. Symptoms follow from obstruction of the ducts in periampullary cancer and from obstruction of the lumen of the gut in the infraampullary or supraampullary growths. Treatment is primarily surgical and usually palliative. Results in general are unsatisfactory.

Carcinoma of the Breast.—H. A. Kelly and R. E. Frick (*Surgery, Gynecology and Obstetrics,* March, 1924), encouraged by the results obtained from five hundred and fifty cases treated by operation and radium, present the following conclusions: Aggressive radium therapy complementary to surgery offers the best prognosis when dealing with malignancy of the breast. The technic of x ray treatment has been difficult but is improving from year to year, just as surgical methods have progressed in the past. Results as yet are not brilliant, as the radiologist is apt to be used as the final court of appeal called in the most hopeless cases, often where every other line has failed and only too often where unscrupulous methods have deprived the patient of all possible hope of relief from suffering.

Gumma of the Breast.—F. E. Adair (*Annals of Surgery,* January, 1924) aims to emphasize the diagnostic points which differentiate gumma of the breast from carcinoma and other malignant growths. He states, in effect, that the great importance of the gumma lies in the fact that during the first three or four periods it so simulates carcinoma of the breast that it is difficult to distinguish, and only with the most minute consideration will it be possible to do so before the tumor has reached the fourth period. After this stage the diagnosis is more simple. The fact that a patient has had syphilis must not have too strong a bearing against the diagnosis of carcinoma; for we occasionally see a carcinoma in a luetic subject. Incidentally this group fare much worse than when carcinoma of the breast is not on luetic soil. There are points which gumma and certain types of carcinoma have in common, namely, stony hardness, sharp circumscription, painlessness, and skin involvement. There are some characteristics of gumma usually not found with carcinoma. These are of diagnostic aid: a history of syphilitic infection, miscarriage, etc.; presence of other syphilitic manifestations; bizarre involvement of the lymph nodes; tumor egg shaped; rarely orange peel skin appearance; gumma grows faster than carcinoma; nipple never retracts unless lesion lies very near it; fluctuation is the rule at one stage; tenderness at this stage; at later stage of ulceration the axillary nodes become markedly involved; Wassermann test positive; therapeutic test with salvarsan.

Influence of Lead on Cell Growth.—W. Blair Bell (*Lancet,* February 9, 1924), reports on his laboratory investigations and clinical observations on the effect of lead on tissue growth, particularly on malignant neoplasms. He found that lead is not only much more toxic to the young and preadolescent man than to the adult and old throughout the vertebrate kingdom, but also that the effects produced by the metal are general in the young and local in the adult. The results obtained were sufficiently promising to encourage further investigation even in hopeless cases. Patients with inoperable neoplasms, if in good condition otherwise, should be given a chance by removal of the growth and immediate postoperative treatment to prevent recurrences. Serious radical operations may be avoided if the patient can be given postoperative treatment. This combined form of treatment with intravenous injections of lead and röntgenotherapy subsequently has given some very encouraging results when the tumor was inoperable but accessible. Ionization, followed by röntgenotherapy, may be advisable in some cases. The author is almost certain that the ultimate mode of treatment in malignant disease will be by the blood stream.

Multiplicity of Tumors, Periodical Growth and Tumor Formation.—E. Hedinger (*Schweizerische medizinische Wochenschrift,* November 1, 1923), states that in a large autopsy material one not rarely finds individuals with several, multiple and different tumors, some of which are benign and some malignant, so that one unquestionably gains the impression that there are individuals with a definite predisposition to tumor formation, in whom a basic differentiation between benign and malignant tumors must not be made. It is still undecided whether this predisposition to tumor formation is familial and hereditary. In view of the significance of malformations in tumor formation and in consideration of the well established fact that malformations are hereditary in principle, a possibility of the predisposition to tumors is more than likely. Individuals, who show multiple tumors in association with beginning malignant tumors, especially cancers, and who are at an age just before or at senility, occasionally show pictures of diffuse proliferation of hepatic and possibly liver cells aside from the tumor formation. Even though senility is characterized by some through the gradual impossibility of new cellular formation, nevertheless some of the biological and morphological conceptions (increased formation of hair, etc.) are in favor of the possibility of a periodical or rhythmical growth even at a later period of life. The proliferations in the liver and kidney, to which might also be added other parenchymatous proliferations, may possibly be viewed in this sense. A definite decision in this matter is impossible because we know too little about the physiological period growth of the metazoa, and particularly of man. Therefore the possibility must be admitted, that the process may not be physiological and periodical, but rather a diffuse pathological growth. At any rate, the occurrence of multiple tumors, namely, in combination with beginning malignant tumors, especially carcinomata, is associated with a tendency toward diffuse growth in one or even different organs. In this way the circumscribed growth of tumors becomes a partial phenomenon of a diffuse, periodical, physiological or even pathological growth.

Prognosis in Giant Cell Sarcoma.—W. B. Coley (*Annals of Surgery,* March, 1924), presents a series of fifty cases, and basing his findings on the end results, offers the following conclusions: Concerning treatment, the author strongly disapproves of the present tendency to forego exploratory operation in tumors of the long bones, and believes that the disadvantages of this procedure have been unduly emphasized by the pathologists, thereby making the surgeons less and less inclined to avail themselves of this most important aid in diagnosis. The greatest objection to exploratory operation is the supposed danger of causing generalization of the disease from cutting into the tumor. That this danger is largely theoretical is shown by the fact that the great majority of cases of sarcoma of the bones that have been cured were cases in which exploratory operation had been performed. Another disadvantage which is claimed for it is the possibility of infection occurring in the exploratory incision. Infection in modern surgical technic should be a rare occurrence. Without an exploratory operation, it is impossible to make an accurate diagnosis in a considerable number of cases; and unless an accurate diagnosis is made, the proper method of treatment cannot be employed sufficiently early to save the life or limb. In the giant cell group of longbone tumors, the author says he would never do a simple exploration, but would perform a thorough curettage as soon as possible.

It is assumed that no bad results will follow the use of radium or x ray in the treatment of longbone sarcoma; and yet there is good reason to believe that if a careful follow-up of all the cases treated by x ray or radium could be obtained, untoward results would be found quite as serious as those that have been observed following curettage. Recently the author amputated the thigh in the case of a benign giant cell sarcoma of the lower end of the femur in an adult, who had originally been treated at another hospital by x ray after curettage and carbolic acid had been applied. In the author's opinion, at the present time there have been no results in the treatment of giant cell sarcoma to justify the substitution of radium or x ray as a method of choice, for curettage supplemented by prophylactic toxins and radium or x ray. A considerable number of permanent cures have been obtained by the latter method, which method has the advantage of greatly shortening the period of treatment and the consequent disability.

The author believes that Bloodgood's latest statistics furnish convincing evidence of the efficacy of the plan of treatment which he advocates, i.e., immediate and thorough curettage; washing out the cavity with carbolic acid, alcohol and zinc chloride (fifty per cent. solution); and if the frozen section shows any evidence of sarcoma, introducing radium needles at the time of operation, leaving the wound open for subsequent study of the tissue filling up the cavity, and for further treatment if necessary. The introduction of radium needles the author believes is unnecessary and prone to lead to infection.

While the author completely agrees with Bloodgood on the method of conservative treatment of central tumors of the long bones, he is even more conservative in that he not only abandons the use of amputation in these cases, but resection as well in a certain group which are clinically and microscopically benign. Furthermore, his series shows that the considerable portion of bone that has been destroyed can be entirely repaired by nature, with restoration of function, without any bone graft. In additon to curettage and escharotics, he believes it advantageous to use the mixed toxins of erysipelas and bacillus prodigiosus, and radium pack, if available, but not until the cavity has nearly closed, thereby greatly decreasing the number of recurrences and hastening the recovery of the patients.

Prognosis in Giant Cell Sarcoma.—W. B. Coley (*Annals of Surgery,* April, 1924), presents the following more detailed conclusions of his work as a whole:

In view of the cases reported by the author, it would seem necessary to modify the opinion so strongly held today by most of the leading pathologists that giant cell sarcoma is always benign and never gives rise to metastases. As far as the author can see, there is only one explanation of these cases which still leaves it possible for one to entertain the theory that giant cell tumors are always benign; and that is, to assume that all of the cases reported by the author, in which metastases developed ending in death, were wrongly diagnosed. It is quite clear that such explanation concedes the whole position. As a matter of fact, however, in the author's personal series of cases, the diagnosis of benign giant cell sarcoma was made not only by competent pathologists, but in many cases by the very pathologists who had made a most careful study of bone tumors; so that if men of such wide experience are unable to differentiate the benign from the malignant type until death from metastases occurs, how much less likely is it that pathologists of ordinary experience will be able to make such differentiation? It must be admitted that the treatment of giant cell sarcoma of the long bones, by radium or x ray, is at present in an experimental stage, and the results thus far obtained do not warrant our giving up the standard method of surgical treatment (curettage) with or without the subsequent use of radium or toxins.

The end results following the different methods of treatment would seem to jusfy us in regarding the best method of treatment of these giant cell tumors as follows: Exploratory operation with curettage of all the tumor that it is possible to remove; swabbing out the cavity with pure carbolic acid and alcohol or zinc chloride; packing the cavity firmly with gauze to control hemorrhage; putting up the limb in a circular plaster of Paris cast if there is any danger of pathological fracture; keeping the cavity clean with Dakin's solution; systemic treatment with the mixed toxins of erysipelas and bacillus prodigiosus for a period of three or four months supplemented with at least one massive dose of radium in the form of a pack, for instance, 12,000 mc. hours at ten cm. distance over three areas, if available, if not, x ray may be used; if the disease recurs in spite of curettage and prophylactic treatment, a second, or even a third curettage may be employed, combined with further use of either toxins or radium; if at the end of six months the disease is still progressing, resection or amputation may be indicated; primary amputation should rarely be performed in any type of central giant cell sarcoma without a prolonged preliminary trial of conservative treatment; clinical evidence of malignancy; rapid growth, breaking through the bony shell should outweigh the histological evidence of a benign giant cell tumor, and in cases of this type, amputation should be performed after a brief trial of conservative treatment, if the disease is not controlled.

Studies Based on Malignant Tumor of the Rabbit.—Wade H. Brown and Louise Pearce (*Journal of Experimental Medicine,* May, 1923) have studied a highly malignant tumor occurring in a rabbit infected with syphilis, in order to determine whether any essential connection could be established between syphilitic infection and the occurrence of malignant growths. The tumor has been successfully transplanted, and is in its twentieth generation. No explanation of the origin of the tumor is put forth, but the history of the growth stamps it as a typical instance of the development of a malignant tumor upon the basis of a chronic inflammatory lesion, in which a syphilitic infecton may have played the part of a predisposing or of an exciting factor. The growth apparently began as a process of a typical epithelial proliferation, such as is common to chronic inflammatory lesions of the skin, and probably differed in no essential respect from the proliferative changes present in neighboring parts of the skin or from those which subsequently developed in the mucous membranes of the mouth and esophagus. The conclusion is reached that the growth in the scrotum represented a neoplasm of epithelial origin which was composed of cells allied to those found in the bulb and root sheath of the hair. The evidence presented is sufficient to warrant the assumption that the factor of foremost importance in the development of the tumor was constitutional rather than local.

In a study of primary transplantation and elimination of a coexisting syphilitic infection the authors found that it was possible to transplant a spontaneous malignant tumor occurring in a syphilitic rabbit by the use of intratesticular inoculation in practically all animals used. In order to eliminate any possible syphilitic infection which might be transmitted along with the tumor, arsphenamine was used. The transplanted tumor showed a high degree of malignancy in the first and second generation, and it appeared that more than fifty per cent. of the animals might be expected to succumb to the effects of the tumor growth within six or seven months.

The Influence of Nourishment on the Growth of Mouse Carcinoma.—F. Ludwig (*Schweizerische medizinische Wochenschrift,* March 6, 1924) was enabled to show that foods poor in vitamines affect the growth of carcinoma and in this way he hopes to explain the etiology of carcinoma. The striking observation that the development of cancer can be inhibited by a lack of accessory food stuffs appears to the author to be sufficient evidence that, in addition to their stimulating effect, these vitamines also play a very important part and that the development or nondevelopment of a carcinoma depends most of all upon the behavior of the vitamines. If these are missing or present in insufficient amount, a stimulating action will not suffice to cause the development of carcinoma. But if there are sufficient vitamines present, any suitable stimulating action will probably produce the development of a carcinoma. It is most probable that the growth promoting factors are responsible, as they are found in all the vitamines, and they seem to be most active in the increased cell division and cell reproduction. The author thus desires to show that the kind of food exerts an immediate effect upon the development of carcinoma. On the basis of this theory new avenues of prophylaxis and of therapy may be brought to light.

Ventral Tumors of the Sacrum.—H. W. Hundling (*Surgery, Gynecology and Obstetrics,* April, 1924), summarizes his findings on various case reports as follows:

Ventral tumors of the sacrum (socalled Middeldorpf tumors) are definitely encapsulated, are usually attached to the periosteum, and tend to erode the bone. The greatest pressure is exerted on the neural and not on the rectal side. Remains of the lower neural canal and the postanal gut appear to form the basis for many of the ventral tumors. There is great diversity of tissue in these growths; all the body tissues may be represented. Opinion seems about equally divided with regard to the monogerminal and bigerminal theories of origin of these tumors. Ventral tumors of the sacrum seldom metastasize, but cause death by infiltration. The blood picture is practically always normal, and the urine rarely shows unusual changes. Systemic reaction of the tumors is mild. Pain, resembling sciatica, and constipation are often the only symptoms. The röntgen ray findings are practically always negative. Treatment consists of the removal or scraping out of the tumor, followed by extensive radium radiation.

Malignant Tumors of the Thyroid.—W. P. Herbst (*Annals of Surgery,* April, 1924) offers the following conclusions:

1. The degree of malignancy in the lesions of the thyroid is according to the order in which they are mentioned: sarcoma, carcinoma, malignant adenoma, and malignant papilloma, sarcoma being the most malignant and papilloma the least.

2. By far the best results are obtained in the cases in which operation is performed before the malignancy has infiltrated the capsule, and this group of cases is the one in which the clinical diagnosis of malignancy is rarely made.

3. Occasional unexpected happy results occur in cases of malignant papilloma found practically inoperable at the time of operation, but in which radical removal of infiltrating growths, and even of glands infected by metastasis, has been practised.

4. There is no grave contraindication to total extirpation, so far as myxedema is concerned, in cases in which all tissue infected by malignancy may be removed.

5. X ray and radium therapy have not been used long enough nor on a sufficiently large number of patients to estimate their true worth.

6. Metastasis to bone is rare in this group of malignancies of the thyroid. The lungs and liver in the order named are the most common sites of distant metastasis.

7. The possibility of malignancy is too rarely thought of in adenomatous tumors of the thyroid in patients of the fifth decade, and this possibility is not used often enough as an argument to urge operative treatment for these patients.

8. A careful followup system should be used in all cases of questionable malignancy, and persisted in for at least ten years before the case is considered benign.

Hippocratic Fingers.—David Campbell (*British Medical Journal,* January 26, 1924), reports a case showing the usual features of hypertrophic osteoarthropathy due to a malignancy (endothelioma) in the left lung. The finger tips became markedly swollen and during a period of four weeks the swelling receded considerably, after which time the swelling returned. The primary pathological finding in all cases of clubbed fingers is edema of the tissues, especially in those lying between the nail and the bone. The author believes that the clubbing of the fingers is due to defective oxidation in the tissues of the extremities, whether produced mechanically by obstruction to the venous return, or by a general lowering of the oxygen tension of the blood in parts of the body where the circulation is retarded.

DIABETES

Diabetes Insipidus and Polyuria.—C. E. DeM. Sajous (*American Journal of the Medical Sciences,* May, 1924), says that Swale Vincent's conclusion that the prevailing attitude concerning the functions of the hypophysis should be reconsidered, in view of the labors of Camus and Roussy, Bailey and Remer, Houssay and others, being fully justified, the line of research which he has reviewed is intended to point out:

1. That it is because the functions attributed to the posterior lobe of the hypophysis by physiologists and others have been erroneous from the start that Swale Vincent's conclusion that the attitude in relation to this organ should be reconsidered now imposes itself.

2. That the investigations of Camus and Roussy and others named do not demonstrate that the posterior lobe of the hypophysis takes no part in the pathogenesis of diabetes insipidus or polyuria; they only show that lesions of the tuber cinereum can provoke these disorders, and that the latter can be produced without the participation or need of a secretion from the hypophysis.

3. That the effects of lesions upon, the slightest contact with, or manipulation of, the posterior lobe; its embryological origin as a neural organ; its histological and chemical similarity to the cerebral cortex; the various disorders which may be strictly localized in it; its autonomous role with the overlying tuber cinereum as shown by decerebrated animals, and other facts submitted, point to this hypophyseobasal area, the name herein suggested for it, as the central starting point of a nerve path which then de-

scends by way of the bulb, the cord and the splanchnic nerves to the kidneys.

4. That the experimental data recorded by Camus and Roussy and others are accounted for by the inhibition or arrest, as a result of lesions practised by them or the pathological sequels of such lesions in the tuber cinereum, of the physiological impulses through the hypophyseorenal path to the vessels of the kidneys, thus causing passive dilation of these vessels, abnormal excitation of the renal cells by the excess of arterial blood thus permitted to reach them and as end result, polyuria or diabetes insipidus.

5. That the beneficial effects of posterior pituitary preparations are accounted for, not by a supposed secretion or hormone in these products, since the actual existence of such a secretion as a physiological entity has never been demonstrated and is controverted by many facts, but by the recognized pharmacological property of these preparations of causing constriction of the arterioles, thus counteracting in the kidneys the dilation of these vessels, which dilation is the cause of diabetes insipidus and polyuria insofar as their relationship with the hypophyseorenal nerve path—a term I would also submit as appropriate—is concerned.

Insulin Treatment.—Leo Pollak (*Wiener klinische Wochenschrift*, January 17, 1924), gives the following indications for the use of insulin: 1. Coma and those precomatous conditions, in which transient results are obtained with sodium bicarbonate; 2. in surgical complications; 3. refractory cases. If some success is achieved with a diet of restricted albumin, there is a relative indication for insulin and the latter need be given only intermittently. The restricted diet of albumin must not be given over too long a period of time as the albumin is indispensable for reparatory purposes. The insulin treatment should be carried out under a continuous control of the urine and the blood sugar. In light cases, if no more than twenty grams of sugar is excreted each day, control of the urine alone is sufficient, so that the patient need not be confined in a sanatorium.

Studies on Diabetes.—In *Endocrinology*, March, 1924, Karl Petren summarizes the contents of his recent book. Even in severe diabetes the nitrogen metabolism is not higher than in health. The necessary condition for reaching the lowest nitrogen metabolism consists in a sufficient caloric intake. In Petren's experience a fat intake up to three hundred grams does not have an unfavorable influence on acidosis, but the deciding factor in the acidosis of severe diabetes is the increased nitrogen metabolism. Fasting days diminish acidosis by lowering nitrogen metabolism, and the same holds for "pure fat days." If the blood sugar threshold, past which glycosuria sets in, decreases during treatment, this has a prognostically unfavorable significance. The author compares the effects obtained by his dietetic method with those of Joslin and Allen and thinks his own results better from a symptomatic point of view. Analysis shows that in a large proportion of subjects an increase of the incretory function of the pancreas set in during the dietetic treatment.

Letters to the Editor.

IVY POISONING—A REMEDY

PHILADELPHIA, *June 18, 1924.*

To the Editor:

Allow me to express my appreciation of the valuable data presented by the Symposium on Dermatology which appeared in the MEDICAL JOURNAL AND RECORD June 4, 1924, especially that portion relating to ivy poisoning.

Will it be asking too much to make a record of an entirely new treatment for the latter malady? For the past fifteen or twenty years I have used exclusively sulphur iodide internally with a saturated solution of epsom salt locally with uniformly satisfactory results.

I have tablet triturates of sulphur iodide which contain one fiftieth grain each, the tablets being one half grain size. The dose is five tablets dissolved in the mouth at intervals of two hours during the first day and at less frequent intervals on the second and possibly the third day, depending upon the serious nature of the invasion. Usually the local irritation and nervous excitement subsides after the first dose and there are no recurring untoward symptoms. That is, relief is afforded *cito, tuto et jucunde.*

Precisely the same treatment is efficacious for beestings. Last fall one of my neighbors stepped up on the porch, as I supposed for a social call, but being seated he said he wished to consult me professionally. It seems a hornet had stung him on the crown a few minutes before and caused rather alarming symptoms—the effect upon the nervous system was felt even in the fingers and toes. Fortunately, I had some of the tablets in the house and had him take five at once, after which he sat down and we talked on various subjects; about ten minutes later when I asked him how he felt he said all the unfavorable symptoms had disappeared. Several days later he told me that he took the prescribed three doses at half hour intervals and when he woke up the next morning all the disagreeable symptoms had subsided and there were no aftereffects.

The physiological basis of this treatment is not difficult to understand—the sulphur iodide neutralizes the poison in the blood stream, while the local application of the epsom salt solution enacts the rôle of an analgesic.

JOHN AULDE, M.D.

A DIAGNOSTIC POINT

NEW YORK, *June 18, 1924.*

To the Editor:

In their interesting and timely article in your current issue entitled Vasovesiculitis Simulating Acute Appendicitis, U. G. Dailey and W. S. Grant were kind enough to pay me the compliment to quote from a recent article of mine on Seminal Vesiculitis, to the effect that I had overlooked "this important diagnostic snag," that is, the possibility of mistaking an acute seminal vesiculitis for an acute appendicitis.

In the article they referred to, I did not discuss the question of differential diagnosis, hence did not mention the point which these authors so strikingly emphasize in their article. However, a more painstaking search of the literature would have shown that in my little book on *Gonorrhea in the Male*, published in 1911, referring to this diagnostic point (page 74) I wrote: "Occasionally cases are seen in which the symptoms are so grave as to suggest the existence of peritonitis or a perforating acute appendicitis."

Again in 1917, writing on the same subject in the last edition of Wood's *Reference Handbook of the Medical Sciences*, page 442, in referring to this diagnostic point, I used the words quoted above.

The point referred to by Dailey and Grant is an extremely important one, and always should be borne in mind before deciding on surgical intervention in cases of supposed appendicitis, particularly in young males.

Medicolegal Notes.

MALPRACTICE ACTION—INSUFFICIENT EVIDENCE OF NEGLIGENCE

In a malpractice action the testimony showed that the plaintiff received a lacerated wound on the forehead, extending through the periosteum to the skull, about two inches long and one quarter inch wide. The defendant examined, cleaned and treated the wound. A trained nurse assisted him, sterilized the instruments used, and was present when he painted the wound inside and outside with tincture of iodine. The wound was open to the skull bone, and the interior for the full length of the cut was plainly visible, and neither the doctor nor the nurse discovered any foreign substance therein. The doctor saturated the wound with antiseptic, stitched it, and dressed it with sterilized gauze, which was held in place by the use of adhesive strips. Thereafter the plaintiff visited the hospital at irregular intervals for three or four weeks. He applied for treatment two or three days after the wound was stitched and dressed. On the occasion of this visit the defendant was not at the hospital. The nurse put fresh sterilized gauze over the wound and requested the plaintiff to call the following day. Plaintiff did not do so, but three or four days later he again applied for treatment. The defendant, at this time, partially removed the stitches, drained the wound, and redressed it.

Two or three weeks later the plaintiff consulted another doctor. The doctor removed the stitches, probed the wound, and found some foreign substance therein. This foreign substance was about the size of a person's little finger nail. The doctor did not know what it was, but after he removed it, cleansed, restitched and dressed the wound, the plaintiff experienced no further trouble from it.

The Louisiana Supreme Court held, Gouner vs. Brosnan, 98 So. 681, that the burden was upon the plaintiff to establish by a fair preponderance of the evidence the allegations of his petition charging the defendant with "negligence, carelessness, want of skill and malpractice" in the methods he employed and the manner in which he treated the plaintiff's wound.

There was conflicting testimony as to the dates, the number of times the wound was dressed, etc., but the outstanding fact which was established beyond dispute, by the testimony of all the doctors who appeared as witnesses, was that the wound was treated by the defendant in the manner most thoroughly approved and followed by the medical profession generally. This testimony was held destructive of plaintiff's contention.

Where there is conflicting testimony, the conclusions of the trial judge, who saw and heard the witnesses, are entitled to great weight, and will not be disturbed unless manifestly erroneous. For these reasons, judgment for the defendant was affirmed.

CHIROPRACTOR MUST HAVE MEDICAL CERTIFICATE TO PRACTISE IN ALABAMA

The Alabama Court of Appeals holds, Fason vs. State, 98 So. 702, in a prosecution for treating human diseases without a license, in violation of section 7564, Ala. Code 1907, that one need not be a "medical" doctor, or one who prescribes drugs or medicines for human diseases, in order to be amenable to this statute against "practising medicine without license." A certificate of qualification from the state board of medical examination is required before one may hold himself out to the public to treat diseases of human beings by any system whatever. A person practising chiropractic must have such certificate, and failing to obtain it he is guilty of violation of the law.

But an affidavit describing the system employed by defendant as "chiropractic or some other system" was held to be indefinite and uncerfain. While the statute mentions "any system" and the system need not be described, yet where a system is named, and in addition thereto "or some other system" is averred, it should be named or the affidavit should aver that it was unknown to affiant. The affidavit was held demurrable for not naming the other system relied on or averring that it was unknown.

In another case in the same court, McClosky v. State, 98 So. 706, it is held that the chiropractor is not excluded or discriminated against by the Alabama statute. He has the same right to apply for a certificate of qualification as does the homeopath or osteopath, and, if granted a certificate by the state board of medical examiners, there is nothing in the law that denies him the right to pursue his method of treatment.

In a prosecution under the statute, the state is not required to prove that the defendant had not obtained the necessary certificate. The defendant must show affirmatively that he had such a certificate.

EMPLOYER'S AGREEMENT TO PAY HOSPITAL FOR EMPLOYEE'S TREATMENT

In a suit by a hospital against the director general of railroads and a railroad for services rendered a railroad employee prior to the period of federal control of the railroads, the Mississippi Supreme Court holds, Vicksburg Infirmary v. Hines, 98 So. 520, that where an employee of a railroad company is received in a hospital for medical treatment, and continued services are rendered to such employee at the special request of an authorized agent of the railroad company, and upon the promise that the company would pay for the services already rendered, as well as future services, and there is no evidence that the bill for such services was charged originally to the employee, such promise or agreement is an original one, having a consideration, and it is not void under the statute of frauds. But the director general was not liable for services rendered the employee prior to the time the President took control of the railroad pursuant to his proclamation of December 26, 1917. Judgment for defendants was therefore affirmed as to the director general and reversed as to the railroad company.

THE USE OF OPIUM AS IMPAIRING THE CREDIBILITY OF A WITNESS

The Alabama Supreme Court holds, Standard Oil Co. v. Carter, 98 So. 575, that the use of opium cannot be introduced to impair the credit of a witness unless it is shown that he was under the influence of the drug at the time of testifying or at the time of the occurrence of the event to which he is testifying, or that his mind was generally impaired by the use of said drug. And in a personal injury case it was held not error to exclude a question to a medical witness as to whether plaintiff had not for many years prior to the injury and subsequent thereto been an "opium habitué," where the question was not followed up by a statement or assurance that defendant expected to show that the habit was so excessive as to impair the memory of the plaintiff.

And Now---for the Weak and Convalescent,

with the heat and humidity of the Summer months at hand, the value of a reconstructive tonic as efficient in action and as palatable and pleasant in effect as

Gray's Glycerine Tonic Comp.

(*Formula Dr. John P. Gray*)

becomes more apparent than perhaps at any other time of the year.

It is in the case of the elderly and infirm—especially those whose digestive organs are inactive and need aiding—that this tonic has shown its superiority to other restorative remedies.

Medical men who derive their greatest satisfaction from the success of the remedies they employ, will find that Gray's Glycerine Tonic Comp. will give them uniformly gratifying results as a tonic restorative when other measures prove to be uncertain and disappointing.

A liberal amount for testing the foregoing will be sent to any practitioner on request

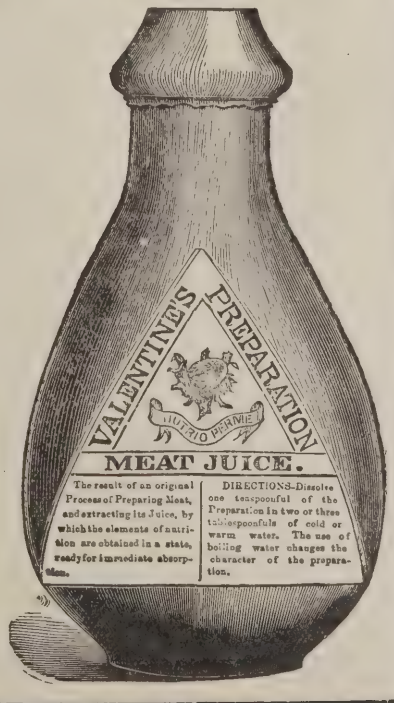
Valentine's Meat-Juice

In **Diarrhoea, Dysentery** and **Cholera Infantum,** in the **Wasting** and **Febrile Diseases** of **Children,** and in the treatment of **Weak Babies,** the **Ease** of **Assimilation** and **Power** of **Valentine's Meat-Juice** to **Restore** and **Strengthen** has been demonstrated in Hospitals for Children.



VALENTINE'S PREPARATION
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Diseases of Children.

W. T. Watt, M. D., *Director Imperial Medical College, Tientsin, China:* "In cases of Infantile Diarrhœa, which weakens and debilitates a child rapidly, I have found VALENTINE'S MEAT-JUICE a great stimulant and quick restorative of vitality. Three years ago when an epidemic broke out in Tientsin, I ordered my staff to try your MEAT-JUICE, which justified all expectations, having been satisfactory to patients and physicians alike."

Dr. Calatraveno, *Late Physician of the Children's Hospital, Madrid, Spain:* "I have employed VALENTINE'S MEAT-JUICE most successfully in cases of convalescence from infectious diseases, and it is especially beneficial for children suffering from urinary weakness caused by extreme debility, as in every case it acted remarkably in restoring their strength with notable rapidity."

Physicians are invited to send for brochures containing clinical reports

For sale by American and European Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,

Miscellany.

Action of Certain Drugs on the Nervous System.—Why and how drugs select special parts of the nervous system for their action is the aim of an investigation under way at New York University by Prof. R. R. Renshaw according to the American Chemical Society. Different drugs, such as nicotine, strychnine, and morphine, act on particular kinds of nerves in particular ways, it is said, but no fundamental evidence has been produced to explain this selective action. Professor Renshaw, the society's statement discloses, has been working on this complex problem, a successful solution of which, it is believed, will lead to the conquest of many diseases of the nervous system which now baffle the medical profession.

It has long been known that much simpler chemical compounds than these drugs have actions on the nerves which for the purposes of research are quite similar. For instance, the action of nicotine on the nerves can be duplicated to some extent with compounds which are simple derivatives of ammonia (tetramethyl ammonium iodide) and are thus far simpler than the ordinary alkaloids. However, Professor Renshaw's research so far has led to the realization that there is much research of a fundamental character in the sciences of physics and chemistry as well as physiology which must be done before any successful outcome may be expected from the major research. For instance, the method by which nervous impulses are transmitted through the nerve fibres is still a complete mystery, although many theories have been advanced. It is impossible to say whether the transmission of a nervous impulse to the brain takes place by a chemical process or a physical one or whether it is an electrical problem, a chemical problem, or a problem involving surface tension.

Discussing the basis for the selective action of drugs on the nervous system, Professor Renshaw made a strong appeal for coordinated, cooperative research. He said:

"The mechanics concerned are extremely complicated and include intricate processes of several fundamental sciences. Unfortunately many physical and chemical phenomena involved are imperfectly understood, and until more information is available in certain fundamentals of these sciences it seems hopeless to expect an adequate explanation of the conduction of the nervous impulse, of the action of drugs, etc. Without such an explanation we have neither a rational basis for curing a large class of diseases nor have we the foundation from which we can systematically develop new curative agents.

"In my judgment a measurable proportion of the funds contributed each year for the advancement of human welfare should be made available for work on the fundamental problems in physiology, physics and chemistry. Too often funds are so restricted that they may not be used to investigate a phenomenon, that may possibly lie back at the beginning of a chain of physiological events the most obvious effect of which is health or disease. Two examples will make my point plain. Recently we prepared a new substance as a possible curative agent for a certain disease. On examination it was found that animals affected with this malady were amazingly sensitive to this material so that very minute quantities caused death. On the other hand normal animals were comparatively insensitive. They could withstand over ten times the amount of material that the infected animal could.

"A more extraordinary situation is shown in a remarkable discovery by Dr. Reid Hunt, of Harvard Medical School. Hunt found that animals fed on a diet of some of the ordinary foodstuffs that we eat daily could have their resistance to a certain chemical, acetonitrile, changed forty fold by feeding them on a different diet but yet made up of our ordinary daily food materials.

"Think of changing one's resistance to a poison from one measure to forty measures by making only such changes in food that any of us might make at any time! Yet, you would have great difficulty getting money to investigate the toxicity of this chemical by which no one is in any danger of being poisoned. Still in my judgment the successful solution of this problem would have the most far reaching effect on human welfare.

"For that matter no one knows what the toxic substances are which are given off to the body fluids by the bacteria of disease. But every student of medicine is familiar with cases of similarity between the action of chemicals and of the toxins as for example the resemblance between the actions of strychnine and tetanus toxin."

Emerods, Mice, and the Plague of I Samuel, Chapter VI.—Dr. D. Fraser Harris (*Annals of Medical History*, December, 1921), says that the Bible verse in question reads: "Wherefore ye shall make images of your emerods and images of your mice that mar the land." The priests and soothsayers of the Philistines recommended this in an attempt to stay a plague that seemed to have some connection with the presence of the Ark of the Lord, which, although it was transferred to many different places, was always attended by various disasters, among them, an epidemic of malignant tumors, and a plague of vast numbers of mice. In a collection at Jaffa is a roughly shaped image of a mouse cut from a piece of white metal, which is considered as perhaps an *ex voto* of the same kind as that referred to in the Hebrew text. The recent knowledge of the etiology of bubonic plague has furnished a possible clue to the significance of these golden mice of the Scriptures; that is, we now know that the bubonic plague, so prevalent in India, is due to the presence in the blood of the Bacillus pestis, and that the usual method of infection is, in the case of man, the bite of a flea from a plague stricken rodent. One of the characteristics of the disease is the development of buboes or tumors. "It it very remarkable," writes the author, "that the priests should have recommended placing in the Ark not only five golden emerods but also five golden mice. The word emerod is a variant of hemorrhoid and seems to be used in this and certain other passages where plagues are mentioned as the synonym of tumor. . . . The interest attached to the emerods in the Ark is, then, that we may take it as exceedingly probable that the plague of I Samuel, VI., 5, was bubonic plague. But a still higher interest still belongs to the five golden mice for they seem to point to some suspected connection between the diseased lower animals and the plague infected people. . . . If they did suspect the connection . . . they anticipated scientific truth by more than two thousand years."

An article in the *Oxford Dictionary* remarks: "The mice and emerods of gold were essentially charms." The writer of this article adds: "It is perfectly possible that the images in the Ark were intended as charms of two different kinds, the emerods against the human plague, and the mice against the overrunning of the land by the vermin. It is certainly exceedingly striking to find the tumors and the rodents associated at so remote a date. . . . 'No rats, no plague,' is an old saying in India."

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

British Scientists to Meet in Toronto.—Preparations are going rapidly forward for the August meeting in Toronto of the British Association for the Advancement of Science, which will be one of the most notable gatherings of English speaking scientists ever convened on the American continent. More than four hundred British scientists and many scientists from the United States and other countries will attend. Among these will be many whose lives and works are world famous. The retiring president, Sir Ernest Rutherford, who did much of the pioneer work on radioactivity, will turn over his office to Major General Sir David Bruce, chairman of the governing body of the Lister Institute, famous for his work on malta fever and sleeping sickness.

Lord Rayleigh will deliver an address on The Scattering of Light. If the World Went Dry is the somewhat startling title of a paper to be delivered by Sir Napier Shaw. The title is presumably to be interpreted in a strictly literal sense, since Sir Napier is a distinguished meteorologist and president of the International Meteorological Committee. Another topic of popular interest will be The Sense of Humor in Children, which will be discussed by Dr. C. W. Kimmins, chief inspector of the educational department of the London County Council.

Popular lectures for children will be a feature of the meeting, three of them being on the program. A series of evening lectures of popular appeal will also be given by some of the distinguished scientists. The regular program will consist of a large number of technical papers to be delivered before the appropriate sections of the association. Some of these papers are expected to disclose new advances in science of the utmost importance.

The inaugural general meeting will take place in the convocation hall of the University of Toronto on Wednesday, August 6th, at which Major General Sir David Bruce will deliver his presidential address on Advances Made in the Knowledge of Disease, with Especial Reference to Methods Developed During the War. The convention will continue through August 13th.

Rural Health Problems.—During 1923 the International Health Board of the Rockefeller Foundation carried on hookworm work in Jamaica, Leeward Islands, Saint Lucia, Trinidad, Porto Rico, Costa Rica, Guatemala, Honduras, Nicaragua, Panama, Salvador, Colombia, Dutch Guiana, Brazil, Australia, Fiji, Siam, Ceylon, India, and Mauritius. An invitation to cooperate with the Government of Mexico was accepted.

Hookworm disease and to a considerable extent malaria and typhoid fever are rural problems. Attempts to control these maladies have disclosed seriously backward health conditions in the American countryside. Typhoid is too often spread by flies, polluted wells, insanitary dairies, and undiscovered carriers. Other communicable diseases are disseminated through the schools. The sanitation of farmhouses and premises is defective. Examinations of rural school children frequently reveal more uncorrected physical defects than are found among town and city pupils. Maternity care and infant hygiene are sadly neglected. Popular knowledge about community health and about personal hygiene, i. e., food, ventilation, and exercise, is meagre and misleading. While the general death rate for the United States has steadily fallen, the decline has been relatively greater for urban than for rural populations. This state of things is not due to causes inherent in rural life but to a failure to extend to the open country the kind of sanitary and health services which have been developed in towns and cities.

The International Health Board has from the beginning of its work had as one aim the merging of specific hookworm measures into general health organizations with the country as the unit. This object was realized first in the South. Later the system spread to other parts of the country until in 1923, 230 counties in 28 states maintained fulltime health staffs. Toward the budgets of 173 of these counties the board contributed. Such aid was in no sense designed permanently to take the place of public funds, but merely to help state and local authorities to prove to communities the value, feasibility, and eventual economy of modern public health work. Similar aid was given for a limited number of rural units in New Brunswick (Canada), Brazil, and Czechoslovakia.

The average county health program includes: inoculation against typhoid, smallpox, and diphtheria; building of sanitary, flyproof latrines; medical inspection of school children, with dental and tonsil clinics; maternity care and infant welfare; control of communicable diseases generally, including special attention to tuberculosis; and education of the community in public and personal hygiene. The typical fulltime staff comprises a health officer, a sanitary inspector, one or more visiting nurses, and an office clerk. Motor transportation is provided. The average total annual cost of such a health service in the counties with which the board is cooperating is $10,000.

Epidemics of Accidents Replace Those of Disease.—Accidental injuries from mechanical devices are rapidly assuming the importance as menaces to life that formerly was taken by epidemic diseases, according to Dr. J. Howard Beard, of the health service headquarters of the University of Illinois, in an address before the American Medical Association. Dr. Beard said:

"An epidemic of injury has succeeded the epidemics of infection. The suicide rate is about that of the whooping cough death rate. Nearly as many people were killed in automobiles at railroad crossings last year as died of scarlet fever in 1920. Fatalities resulting from automobile accidents in 1923 are about the same as those from diphtheria and scarlet fever combined. Accidental deaths in industry are approximately equal to the sum of the deaths due to measles, whooping cough and diphtheria. There are 700,000 persons injured yearly in their occupations, whose disability causes a loss from work of not less than four weeks. Industrial poisoning produces its great quota of disease and death, and in some of the more sanitary cities, the exhaust gas from automobiles causes more deaths than the typhoid bacillus. Intelligent public sentiment, fostered among employers, employees and chauffeurs, as well as in institutions of higher learning, is the only way of coping with the accident disease."

Brazil's Final Bout With Yellow Fever.—The outstanding feature during 1923 of the systematic, concerted attack upon yellow fever in which the International Health Board of the Rockefeller Foundation has been engaged since 1916 was the decision of the Brazilian Government to undertake a definite campaign to eliminate the disease from the seed beds along the northern coast from Pará to Bahia, where fever still appears from time to time. The Board warmly welcomed the invitation of the Brazilian authorities to have a part in this work. Noguchi, the discoverer of the yellow fever organism, sailed for Brazil in November to make further studies and was soon followed by staff members with equipment and supplies.

This latest, and it is to be hoped final, bout with yellow fever in Brazil recalls the brilliant way in which the capital was freed from yellow fever under the leadership of that distinguished scientist and able administrator, Oswaldo Cruz. Graduated from the University of Rio de Janeiro, for four years a student and investigator at the Pasteur Institute in Paris, he overcame all obstacles and opposition and made Rio de Janeiro safe.

Oswaldo Cruz had watched with eager interest the progress of yellow fever control. Finlay's early (1881) suggestion that the disease is spread by a mosquito, Ross's discovery (1897) that malaria is transmitted in this way, the indisputable proof by the United States Army Commission under Reed in Cuba (1900-1901) that the fever is communicated solely by the bite of the female Stegomyia mosquito, the success of Gorgas in wiping out yellow fever by mosquito control of Havana, in Cuba, and in the Panama Canal Zone, convinced the young Brazilian that the same methods could be successfully applied in his own city of Rio. Appointed Director of Public Health and loyally supported by President Alves, he gradually overcame traditional prejudices, professional opposition, the persistence of antiquated methods, and apprehensive interests of many kinds, until the annual deaths from yellow fever had fallen from 984 in 1902 to 0 in 1909.

Oswaldo Cruz's death in 1917 prevented him from following as he would have done with so much satisfaction the later success of the campaigns organized by the International Health Board; the formation of national yellow fever commissions in Mexico, Central America, and in Northern South America; Noguchi's discovery of the causative organism and his preparation of a vaccine and a serum; the clearing up (1918-1919) of Guayaquil in Ecuador, the chief endemic centre; the exploratory expedition (1920) to the West Coast of Africa to investigate cases reported there; the elimination of the fever from Peru (1921); the quick control of incipient epidemics in Central America; and the active participation of the Mexican Government in the movement until by 1923 it was possible to make a most encouraging report. The situation in 1923 may be summarized as follows: No cases reported from Mexico, Central America, Ecuador, or Peru; outbreak in Colombia promptly put under observation; well organized control measures under way in Northern Brazil and workers in training to resume study and observation along the coasts of West Africa from which cases of yellow fever have been reported.

Radium Therapy in Gynecology*

P. BROOKE BLAND, M.D.,

Philadelphia, Pa.

We have been using radium in the common gynecological lesions for approximately nine years. Our first application was made for carcinoma of the uterus. This was administered on January 6, 1915. Since that period we have employed radium more or less constantly. We have not used it to the extent of some of our contemporaries in Philadelphia, but quite enough, I think, to present a comprehensive view of its value in the specialty in which I work, gynecology. I may add further that in certain instances we have found it to act with noteworthy success, while in others it has as notably failed. Hence, like most of the resources at our command, it cannot be regarded as a specific for the various conditions arising in the uterus or its appendages; although one must admit as a therapeutic measure in certain conditions it occupies first rank.

In uterine cancer, for example, so far as successful therapy is concerned, it is the equal of surgery, or, indeed, even more than equal; first, because the results as regards palliation and socalled cure are best served by this element, and second, because it does not entail any special risk or mortality; factors which always must be considered in operative therapeutics.

Radium, like surgery, often is associated with phenomena which one cannot fathom. It sometimes succeeds in cases presenting a hopeless aspect and, like surgery, it utterly fails in others presenting a hopeful appearance. This is due probably, as has been mentioned by various authors, to some cellular or biological principle which we are unable to demonstrate or comprehend.

In gynecology, as in other departments of medicine, radium may be applied in one of three ways, namely:

1. In the form of radium capsules (metal vehicles —brass, silver, gold or platinum—containing glass tubes of a radium salt).

2. In radium needles (metal needles containing the element encased in glass tubes in the form of one of its salts).

3. In the form of glass pearls (containers of radium emanation or radium gas).

It is not customary to apply the element itself. A radium salt is usually employed. This may be applied properly screened within the genital tract or through the abdominal wall, likewise properly screened. Radium is now frequently employed in combination with deep x ray therapy through the abdominal wall. In a voluminous literature most favorable results are being reported by the use of the combined method. Personally, I have not had sufficient observation to speak of the merits of this plan, but both in this country and in Europe, encouraging results have been recorded.

Of the local agents used in the treatment of pelvic disease, radium, the x ray and radioactive substances are of the greatest value and are the outstanding local measures in use, and of these, radium occupies the foremost rank. Indeed, it fulfills a need that cannot be supplied by any other remedy.

The use of radium therapy in pelvic disease is in its infancy, but it has, in a measure, revolutionized the treatment of certain lesions heretofore regarded as wholly surgical. What the future holds for radium, in a more extended application to pelvic affections, it is impossible to say.

While the substance is of the greatest value, yet a word of warning may not be out of place even from an enthusiastic proponent of this plan of treatment.

Radium, as you all know, is being universally employed for a great variety of conditions, probably too universally and probably, too, for a greater variety of conditions than the means justify. This, however, is true of most innovations and radium is still in the stage of innovation. Enthusiastic use often evokes a certain amount of abuse and that radiotherapy has been abused, no one will deny. That radium is not a cureall the most interested and experienced radiotherapist will acknowledge, though it is being used and with variable success in a greater variety of conditions than any other single substance.

We believe still greater success awaits a wider application of the remedy and where the next step will lead it is impossible to say. Perhaps the gap between the x ray and radium, wide as it is, will be exceeded by the gap between radium and the next most powerful radioactive substance which awaits inevitable discovery. We may, through the subtle influence of agents endowed with still more powerful radioactivity, find a sovereign remedy for cer-

*Presented at a regular meeting of The Bucks County Medical Society, February 13, 1924.

Copyright, 1924, by A. R. Elliott Publishing Company.

tain diseases of the pelvis and of the medical sovereigns today, if I may use that term, radium, unquestionably, stands supreme.

APPLICATION

Radium in its elemental state is unstable, hence for therapeutic purposes, rays of its various salts are employed. The salts generally used are the chloride, carbonate, bromide and sulphate. The latter two, owing largely to their insolubility, are most commonly used.

The application of radium may be made upon the vulva, within the vulva, within the vagina, the cervical canal, the uterine cavity or over the abdominal wall (Fig. 1). In certain instances it may be desirable to combine an external with an internal application (Fig. 2).

The salts of radium are supplied in glass capsules and these are encased in metal tubes of steel, brass, platinum, silver or gold. These metal containers are used, first, to prevent the loss of the radium salt, and second, to act as a screen to the alpha and beta rays. Radium salts are also supplied in platinum, steel or silver needles and also in glass capillaries or pearls containing radium emanation or radium gas. Either of these methods of application may be made separately or a combination of one or more may be used. Before applying radium it is necessary to provide further screening, and this is done by covering the metal tubes with dental rubber, the object being to screen or filter the alpha and beta rays, because therapeutically the penetrating gamma rays are the most effectual and, therefore, the most desirable.

DOSE

The dose of radium is expressed in milligram hours or millicuries, abbreviated mghrs. or mcc., each representing an application of one hundred milligrams of radium or radium emanation for one hour. In other words, the exposure of a patient to one hundred milligrams of radium for one hour is equivalent to a one milligram hour dose; ten hours to a one thousand milligram hour dose; twenty hours to a two thousand milligram hour dose and twenty-four hours to a twenty-four hundred milligram hour dose. The latter represents the usual dose applied to malignant disease of the cervix, either of the early borderline or inoperable type. In the simple functional menorrhagias of young women and women in the early childbearing period of life, in whom menstrual and reproductive functions are to be maintained, the dose of radium should be relatively small and applications should be made with great care. In these it is our custom to apply fifty milligrams from four to six hours or, in other words, to administer a two hundred to a three hundred milligram hour dose. This, in the simple functional menorrhagias, is usually quite sufficient to diminish the excessive menstrual flow without stopping the menstrual cycle altogether.

It has been pointed out that pregnancy after radiation occurs only occasionally, so in the reproductive period of life, relatively small doses should be used. Small doses are usually quite sufficient to control the menorrhagias of myopathic uteri and also in hemorrhage resulting from socalled cystic oophoritis. In the simple menorrhagias, as already indicated, a single dose usually relieves the symptom. A second dose may be employed but, as a rule, is not necessary.

In uterine myomata, especially in women approaching, or those in the menopausal years, larger doses with repetition is sometimes necessary and in uterine malignant disease, especially inoperable malignancy, still larger doses with repetition may be required.

TISSUE SENSITIZATION

It has been definitely shown that all tissues, both normal and pathological, are variously affected by radioactive substances. The normal adult tissue cell, however, is much more resistant, less sensitive and less likely to injury than the embryonic actively growing pathological cell. The younger the life of a neoplastic mass, therefore, the more readily influenced is its cell character. With regard to neoplasms, it has been demonstrated that myomata stand first in sensitiveness to radiation, sarcomata occupy second place and carcinomata, the most resistant of all, third place.

BIOLOGICAL ACTION

With respect to the biological action of radium, it has been demonstrated that there are three zones of reaction. First, immediately surrounding the point of application there occurs more or less destruction of the neoplastic cells with fibrosis. Second, beyond the point of application there is only partial destruction with a less degree of fibrosis. Third, still more remote from the site of application, there is, instead of destruction, more or less cell stimulation. This description of the direct influence of radium applies especially to neoplasms of a malignant nature.

Dewell Gann, Jr., asserts that radium possesses, first, a general selective action, and second, a selective destructive action, general selective action, in that it destroys all tissue with which it comes in contact, and especially selective action in causing regression or even wholly destroying neoplastic disease. By some authors this statement is not accepted. Nevertheless, it does influence both normal and pathological tissue, and it does seem to cause regression or destruction of neoplastic disease without inflicting severe or permanent damage on the normal surrounding structures, provided it is properly used.

One may say that radium, then, is more or less destructive both to normal and pathological tissue. But normal adult tissue cells, owing to greater maturity, are infinitely less influenced than the immature embryonal tumor cells. The intensity of the histobiological changes occurring after radiation, depend upon the dose applied as well as the local reaction of the disease and the systemic response of the patient.

Henry Schmitz, who has made an extensive study of tissue exposed to radium, while deprecating routine biopsy, advocates the excision of tissue for diagnostic study immediately before the application of radium. I wonder if the danger of autovaccination of malignancy, after diagnostic excision, or diagnostic curettage, if it occurs at all, is as reprehensible as some investigators would have us believe. Personally, I should prefer, in case of doubtful malignancy, to run the risk of autovaccination, if such exists, before being submitted to either radiation or operation.

Schmitz, after the initial diagnostic excision is made, followed by radiation, advocates repeated test excisions at intervals of from eight to fourteen days

for a period of six weeks, at a time when ordinary tissue alterations are complete. In a large series of cases Schmitz made postradiation tissue studies after three, six, eighteen, and twenty-four months. In the latter tissue was collected from patients, postmortem. The microscopic examination of tissue

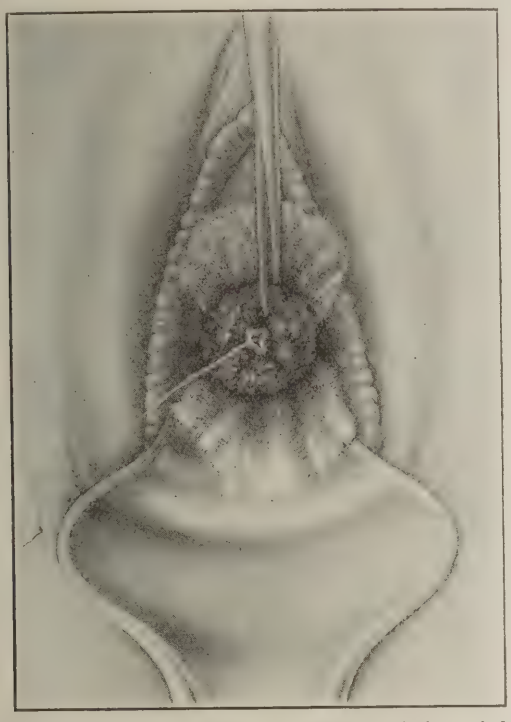

FIG. 1.—Application of radium capsule in cervical canal for carcinoma of cervix.

radiated demonstrates most vividly the power and influence of this method of treatment. The changes are pronounced and constant. The alteration in cell architecture, following the application of radium, is described by various authors, including Schmitz, in four stages, as follows:

1. During the first stage there is observed serous infiltration, characterized by swelling of the cells and their nucleus with a beginning invasion or exudation of lymphocytes and polynuclear leucocytes. These phenomena may occur as early as the third day and in nearly all instances they are observed by the eighth or tenth day.

2. There follows in the second stage more or less degeneration of the cell nucleus, the cell protoplasm and the cell wall. These cellular alterations are indicated by fragmentation of the nucleus, cytolysis, granulation, and vacuolation of protoplasm. Achromatism and cessation of mitosis are all also observed during this stage.

3. The changes in the third stage are of an inflammatory nature, as shown by leucocytic and lymphocytic infiltration, proliferation of the stroma and the formation of fibroblasts with rapid growth of bloodvessels. Phagocytosis occurs simultaneously, the white blood cells acting as microcytes and the fibroblasts as macrocytes.

4. The fourth stage represents a period of reconstruction or repair of devastated tissue and destroyed tumor cells. Reconstruction or replacement is effected by the formation of granulation and fibrous tissue which finally becomes covered with epithelium, and in which numerous capillaries are found. Should the dose of radium be excessive, necrosis with avascular fibrosis takes place.

The changes herewith described begin, as has been demonstrated by numerous investigators, within a few days after the application of the element and may continue for two or three months. The maximum influence is usually evident by the end of the fourth or fifth week.

The alteration in tissue as outlined in the first two stages results directly from the action of the radium upon the neoplastic cells. The third stage is the local response of tissue to an irritant. This represents an inflammatory reparative process. The fourth stage represents a stage of reconstruction and healing, either by regeneration of the surface epithelium or by necrosis, followed by scar tissue formation.

SYSTEMIC REACTION TO RADIUM

In addition to the local response to the irritant, if I may use that term, there is in nearly all instances systemic response as well. Constitutional reaction is extremely variable both in onset and severity. It depends upon the dose administered, the character of the rays, the type and location of the tumor, and the general physical and psychical condition of the patient.

The constitutional reaction is due to certain alterations brought about in the blood from the direct absorption of the rays by the white blood cells and from the absorption of proteins and ferments liberated by the radiated growth. Marked constitutional response, provided the dose be small or moderate and the general physical and psychical condi-

FIG. 2.—Portraying position of the radium needles and emanation pearls for advanced carcinoma of the cervix.

tion of the patient relatively good, is not marked, though in most cases there is more or less toxemia.

Prostration of a varying degree is sometimes seen, but probably the most common systemic response to radiation is gastrointestinal irritability. This occurs first in the form of anorexia, but more commonly as nausea and vomiting. This may be moderate and of short duration, but sometimes it is severe and endures, as in one case, for three or four days or even

longer. Acidosis, in this patient, was extremely profound. In this connection the element of nervousness must always be taken into account and, while the patient to whom I referred was of the neurotic type, we felt, notwithstanding, that her gastric irritability was truly an evidence of acute toxemia, or an instance of true postradiation, nausea and vomiting. Sometimes there is more or less disturbance in the thermal system, manifested by subnormal temperature, especially if the toxemia be profound, but in most cases there is a mild elevation. This is coincident with a moderate acceleration of the pulse rate. The thermal and circulatory phenomena are both, as is gastrointestinal disorder, dependent upon the absorption of rays and toxic material and the susceptibility of the patient.

Occasionally headache is a sequel of radiation and it may be moderate or severe. As a rule, it is not marked.

Bladder irritability and vesical tenesmus with frequent and painful urination are not infrequent. This may be of very short duration or it may last for three or four days or even longer. Bladder irritability, no doubt, is due to faulty protection of the bladder wall with direct action of the rays thereon. Another postradiation sequel, due also to faulty protection, is rectal tenesmus, sometimes amounting to moderate and in some instances, to severe pain. This may disappear within twenty-four hours or it may last for several days. In a few cases the rectal distress is almost intolerable, so much so as to require a long interval of rest before reradiation can be performed. In very rare cases bladder and rectal irritability may be so intense and the suffering so great that patients will reluctantly submit to subsequent treatment. I have had two or three experiences of this kind. With proper screening and proper doses symptoms arising in the urinary or fecal canal may be reduced to a minimum, if not wholly prevented. In this connection it may not be amiss to mention that in certain cases with extensive tissue destruction, fistulæ may form between the vaginal canal and adjacent urinary and fecal conduits.

I have seen both urinary and fecal fistulæ result from radiation. A large vesicovaginal fistula occurred in one patient after a twelve hundred mghr. dose. This was given prophylactically, preceding and following a radical hysterectomy for extensive cervical carcinoma. In another patient suffering from inoperable carcinoma of the cervix, radium was applied rather heroically, probably too heroically, because a large rectovaginal fistula developed. Both these patients were operated upon subsequently, and both are living and well at the present time. The first patient was treated in February, 1918, and the second in August, 1922.

In a small percentage of cases tissue destruction may be intense and the systemic absorption of both the rays and toxic matter so great as to give rise to alarming symptoms, and even cause death, though death from the application of radium, fortunately, unless complicated by some serious intercurrent condition, is exceedingly rare.

We have never observed a radium fatality and we have personal knowledge of but one death occurring in Philadelphia. This patient was radiated by one of my colleagues for extensive cervical carcinoma of the cervix. Death from sepsis occurred three weeks subsequent to the application.

One of the most prominent systemic reactions occurs in the circulating blood. This not only is observed in patients radiated, but it sometimes occurs in individuals who handle the element more or less constantly. Hence, in those exposed repeatedly or for long periods, either operator or patient, it is customary to make systematic blood analyses. If signs of leucopenia are observed, the affected individual should be temporarily withdrawn from exposure to the rays. In patients who manifest a mild or moderate leucopenia, restoration of the blood quality is usually prompt. In severe and persisting cases blood transfusion may be necessary. Finally, the systemic reaction to radium as regards the blood changes is found less marked in individuals of relatively normal health, while in those impoverished by long persistent bleeding, by neoplastic toxemia, by poor resistance in general, and by undue susceptibility to the rays, the reaction is likely to be more intense.

Here it is quite in order to point out that radiation of malignant tissue either by x ray or radium, through its action upon the blood, excites a certain degree of immunity. It is thought that the liberation and absorption of proteins from the devastated cancer cells produces specific antibodies for other cancer cells or metastatic cells in the various tissues of the patient. This conviction is confirmed by the investigations of Morison, Wedd, Russ, Blumenthal, Behen and others. From experiments carried out both upon animals and upon human beings, Behen, by transfusing the blood of radiated animals into animals which had not been radiated, produced the same leucocytic and lymphocytic reaction as observed in those submitted to direct radiation. On the other hand, transfusing blood of nonradiated animals into controls did not show these significant phenomena.

INDICATIONS FOR RADIUM THERAPY IN GYNECOLOGY

Radium may be used in the following pelvic lesions, both functional and organic:

1. In primary and recurrent malignant tumors of the uterus.
2. In benign tumors of the uterus.
3. In the simple menorrhagias and metrorrhagias in which no cause can be determined.
4. In the menorrhagias and metrorrhagias due to cystic oophoritis.
5. In menopausal hemorrhage.
6. In endocervicitis and cervicitis, associated with leucorrheal discharge.
7. In dysmenorrhea.
8. In malignant disease of the vulva and vagina.
9. In benign and malignant disease of the bladder.
10. In malignant disease of the rectum.
11. In the menorrhagias and metrorrhagias of myopathic uteri.
12. In vulval leucoplakia and vulval and anal pruritus.
13. In localized recurrent malignant nodules following amputation of the breast.

In all the conditions herewith enumerated, radium will prove of utmost value, but it finds its greatest service in uterine malignancy and in uterine myomata.

RADIUM IN UTERINE CANCER

The uniformly discouraging results obtained by the radical operation for cancer of the uterus have led some writers to advocate radiation instead of

operation, but this teaching, as yet, has not been universally accepted. If applied early, surgery, we believe, still offers the most hopeful outlook for permanent cure, but that radiation is of immeasurable value in the indications to be mentioned later, none can deny.

1. As a prophylactic preceding and following operation.
2. As a general adjunct to the surgeon.
3. As a palliative of the first rank.
4. As a curative in certain cases.
5. As of great value in all.

The judgment, in general, today indicates that radium is most influential in the early stage of the disease, the young or immature cell stage, and this is the period when cervical carcinoma likewise is most responsive to radical operation. We believe, therefore, with most observers, even the most ardent radium enthusiasts, that as a curative measure in the early stage operation should receive first choice and radium second. Future experience may force a revision of this opinion.

Clark, who has had wide experience both in the operative and radioactive treatment of cervical malignancy, believes that: "At present we are not justified in using the element as a curative agent in the operable type of the disease." There is a wide divergence of opinion also regarding the choice of operation or radiation in the socalled borderline cases. Most observers believe that as much, if not more, can be accomplished by radiation as by operation. Statistics seem to confirm this view. It is well known that operation, except in the very early stage of cervical carcinoma, nearly always fails.

Otto Von Franque asserts that the number of five year cures of borderline cases for both operation and radiation are about equal and average about twenty per cent. Zweifel reports 27.5 per cent.; Franz, 28 per cent.; and Kerher, 27.9 per cent.

Von Franque asserts that the results for radiation and operation, in operable cases, are about equal also and average fifty per cent. Zweifel reports a five year cure of 50.8 per cent., Doderlein forty-eight per cent., and Kerher fifty-eight per cent. These results are far better than those which obtain in this country, some men fixing the five year operative cures at ten per cent. or less.

In the inoperable type Von Franque does not believe that more than six to ten per cent. of the cases are cured by radiation, although he quotes Kerher who lays claim to a cure in seventeen per cent.

W. P. Graves favors operation in cases regarded as operable because it removes, he says, more of the disease than radium, as well as the occasionally diseased regional lymphatic glands. Lymphatic gland infection, he affirms, is too distant for radium to affect lethally.

In this relation it is well to recall that Wertheimer asserted that he never saw a patient with uterine cancer recover permanently who had frankly infected lymphatic glands. This is quite in accord with our own experience. I should like to add also that many authors, including Graves, do not believe in preoperative radiation as a prophylactic. They object to the method on account of certain "technical difficulties" involved.

Personally, I do not believe that preoperative radiation does any material harm; on the contrary, I believe it does some material good.

L. Mayer says he has noted a marked decrease in the deaths from peritonitis following operation in patients whom he had previously radiated. This author also found that preoperative radiation increased his operability from fifty to sixty-five per cent. Owing to the cessation of bleeding and control of toxemia after radiation, it is quite natural to suppose that patients are better equipped to withstand surgery.

Personally, I am firm in my conviction that preoperative radiation of cervical cancer is, indeed, worthwhile. I believe, moreover, that it is a wise postoperative expedient as a prophylactic, provided it is applied with due regard to impending irritation of the bladder and rectum if not organic destruction.

However, the indiscriminate, too frequent, as well as too long, postoperative exposure of both the urinary and fecal canals may, and occasionally does result in a slough with subsequent fistula formation, as indicated in the two patients to whom reference has already been made.

Wertheimer, in writing of the prophylactic influence of radium with reference to metastasis found, upon examining thirty-two patients postmortem, that radiation did not excite but rather hindered metastasis. Patients who were not rayed showed metastasis in fifty-four per cent., while in those radiated the percentage of metastasis was forty-eight. This in itself would seem an additional, if not a convincing reason, why radiation should be used in a prophylactic way.

RESULTS

Bailey and Healy report the results of nine hundred and eight cases of uterine cancer treated by radium at the Memorial Hospital in New York. Their observations support the experience recorded by Kelly and show that he was nearer right than wrong. The approximate results reported by Bailey and Healy with reference to five year cures in cervical cancer are portrayed in the following table:

Type	*No. of Cases*	*Percentage Cured*
Early operable	45	71
Borderline	33	24
Recurrent	168	22
Advanced or inoperable	190	7.4

Of three hundred and thirteen cases reported by Clark and Keen, one hundred and twelve patients are living and two hundred and one are dead. Of the three hundred and thirteen cases, all but twenty-three involved the cervix. Of the twenty-three body cases, twelve patients were alive after from three to six years. The remaining fourteen are below the three year limit, but all are in excellent health.

Recaséns, who has been employing radium in cancer of the cervix for more than ten years, is unusually enthusiastic, perhaps too enthusiastic, because he says he has relieved or eradicated the disease in from sixty to seventy per cent. of the four hundred patients upon whom the element has been used. He reports numerous cures extending over a period of three, four and five years, respectively.

J. W. Ross reports four hundred and seventy-five cases of cervical carcinoma in which various forms of treatment were applied. He believes that in early

cases surgery alone provides good results, but he very aptly asserts that surgery and radiation combined gives slightly better results than surgery alone. In the operable cases, but not necessarily in the early stage, the combined method—radiation and operation—gives the best results. Probably later on radiation will replace operation, even in early cases, but as yet most authors are not satisfied that radium is superior to surgery, nor have more than a very few had the temerity to adopt a plan which is still in an uncertain period of development.

A word in this connection may not be amiss regarding the combined method of treatment, namely, x ray and radium.

R. Duncan, in writing of his experience, quotes Janeway, who tabulated six thousand cases of uterine cancer observed both in this country and in Europe. This tabulation shows that of every one hundred patients applying for treatment, sixty are beyond the stage of operability. Of the forty per cent. subjected to surgery, seven or eighteen per cent. will die as the result of the surgical procedure and eight will probably remain well. Twenty-five will have a recurrence. Hence with the sixty unsuitable for radical surgery, the seven who die from the operation and the twenty-five in whom there is recurrence, leaves only eight who will remain well. Therefore, ninety-two out of every one hundred patients are inevitably doomed unless some other method than surgery is provided for their relief.

Duncan shows that the results of treatment are materially improved by high x ray voltage combined with radium. He advocates keeping the patient in the hospital for a period of from five to seven days and applying during this time one thousand to six thousand mcc. of radium. After the local reaction subsides, or in from six to ten days, the patient is given a thorough radiation with high voltage x rays. This author reports three hundred patients thus treated prior to 1922. One hundred and twenty-two, or forty per cent., of these patients were clinically well from two to seven years and of this number ninety-seven, or 36.4 per cent., are still clinically well.

In a personal letter Dr. Howard Kelly states that in cancer of the cervix he prefers radiation to operation, though he does not always hope for permanent relief, especially if the disease is extensive and well beyond that structure. The improvement in extensive cases was only temporary, he found, but even in these, the application, he asserts, is worth while. In cancer involving the uterine body, Dr. Kelly, in accord with most men, recommends radiation if constitutional affections, such as kidney, heart, pulmonary, arterial or other disease, contraindicate operation.

Kelly and Burnam believe that every inoperable cancer of the cervix and vagina, provided general metastasis is not present, stands a chance at least of one in four of being cured. With the joint use of radium and operation in the operable types a curable rate may be raised in three out of four or better.

As early as 1915, Kelly and Burnam reported two hundred and thirteen cases of cancer of the cervix and vagina treated with radium. One hundred and ninety of these were classed as inoperable. Fifty-three of these patients were clinically well after a period of five years. One hundred and seven were markedly improved. Thirty-seven were unimproved.

Burnam also reports four hundred cases of genital cancer treated with x ray and radium combined, with a recovery of 46.91 per cent., and in another series of one hundred and fifty-five cases treated by the combined method, Burnam obtained eighty-three or 55.51 per cent. recoveries. In two hundred and three cases of uterine cancer subjected to operation there were ninety-eight or 48.27 per cent. recoveries.

J. and J. L. Ransohoff reported twenty-five cases of uterine cancer radiated with eleven recoveries. Three of these were operable and eight inoperable.

H. Bailey records one hundred and twenty cases in which twenty-one per cent. of the patients showed such improvement as to justify the possibility of cure, but of these only fifteen per cent. were well after two years.

R. H. Boggs believes that one fourth to one third of the hopelessly inoperable cases will totally disappear by the application of radium.

Recaséns, of Madrid, believes that sixty per cent. of cures can be obtained in all cases and in nearly all, if the disease is localized and early treatment instituted. He states that one hundred per cent. of cures should be obtained in the incipient stage of the disease and he bases this assertion on sixteen early cases treated with complete regression and recovery in all. Most of these patients have passed a three year period without recurrence. In addition, he treated one hundred and eighty-two inoperable cervical cases—forty-seven in 1914—and in these twenty-nine patients were still well in 1919. In 1915 he treated seventy-nine and forty-five patients were still well in 1919. In cancer of the body he obtained fifty per cent. of cures. He concludes by stating that in seventy per cent. of his inoperable and ninety-five per cent. of his early operable cases the patients have recovered. In body cancer, however, he prefers operation, if no systemic contraindications are present.

In 1919 Henry H. Janeway reported thirty cases of genital cancer radiated with a posttherapeutic history varying from three and one half years to six months. Seventeen of these were primarily of the cervix, four recurrent, four of the fundus and five of the vulva. Of the seventeen patients, one was well after three and one half years; one at the end of three years; one at the end of one and three quarter years; nine beyond one year and all showed regression. Five of the seventeen cases recurred after the first treatment and are being treated, he says, but are showing a poor outlook. The four body cases showed good results. Of the four recurrent cases, two showed promise of cure and two were unimproved. Of the five vulval cases two obtained a good result and the others showed such marked improvement as to expect cure.

DOSE IN CANCER

The dose should not be less than one hundred mgs. for a period of from twelve to twenty-four hours, but by some larger doses are being used. If there is involvement of the bladder or rectal wall, the dose should be smaller and given with extreme caution. Repetition is made in four weeks, if necessary.

Some writers recommend a longer interval and a long intervening period is recommended, particularly if the disease involves the bladder or bowel. Two or three doses may be given—sometimes more—according to the local result and systemic reaction of the patient. Repetition, however, is not practised to the extent it was a few years ago. A second or third dose may be employed. Moderate repetition, if wisely practised, may not do any harm. It may do some good, though whatever good is accomplished (and the greatest, too) is brought about by the first dose—the first application.

My personal experience with radium therapy in cervical carcinoma has been limited almost exclusively to the treatment of the hopelessly inoperable type. Of one hundred and twelve cases treated, I can report only two which one can designate as cured, covering the five year period, though every patient was benefited both locally and systemically.

Notwithstanding, the growing trend of applying radium to the borderline and socalled early cases, we still believe, owing probably to lack of courage, and a clinical environment, that in early cases, if not in those classed as borderline, that operation and not radiation, for a problem always vexatious and always uncertain, despite growing reports to the contrary, offers the most hopeful outlook for ultimate and permanent recovery. I do, however, hold an open mind that with wider application and more extensive observation, a few years hence may cause one to reverse this opinion, an opinion now shared by the large majority of men active in pelvic work.

We have been using the agent as a prophylactic also before operation and for a similar reason after operation. As a preoperative prophylactic, radium should be applied within the cervical canal (2,400 mghrs.) four weeks before operation. We are convinced that this is a good plan to follow, because it destroys or seals by fibrosis the exuberant mass teeming with all forms of pathogenic bacteria and hence must hinder, to some extent at least, the propagation of postoperative infection.

This course we have pursued in a large number of cases and have had no cause for regret. The technical difficulties with greater danger of infection, preoperative radiation is said to produce, we have never encountered. As regards the palliative action of radium one may, without qualification, say that it will do more than any other known agent at our command. First, locally by temporarily, if not permanently, inhibiting the growth, allaying discharge, controlling hemorrhage and to a less extent alleviating pain. Second, by providing the patient with, temporary at least, if not permanent systemic improvement.

(*To be concluded*)

Tuberculous Disease of the Spleen*

FRANCIS REDER, M.D., F.A.C.S.,
St. Louis, Mo.

Much of the difficulty in reaching a differential diagnosis in conditions cursorily diagnosed as splenomegalies must be ascribed to the stage of the disease when seen by the physician. There are now recognized several clinical types of splenomegalia, the proper classification of which, i. e., the individualization of syndromes, demand the most delicate refinements in diagnostic skill. In many instances the etiology and pathology of these splenic enlargements present a clinical picture so strongly interwoven with allied characteristics that a trustworthy differentiation becomes almost impossible.

If it were possible that our knowledge of the physiology of this organ encompassed a greater latitude than it does at present, we could perhaps speak with greater certainty upon its functional perversions.

In most splenic tumors it is the blood examination that has given the greatest assurance in discriminating between these clinical types. It is the blood examination only which can give us the convincing evidence upon which a pathological differentiation can be made possible. The anamnesis, the symptoms and physical signs are valuable assets, but without the study of the blood, the clinical picture will still remain strongly befogged. Not infrequently a patient will consult a physician for a perceptible abdominal enlargement with a history so vague that it is impossible to fix the date of the commencement of the pathological process. It is only by close questioning that some of the data can be obtained which may elucidate a better understanding of the cause of the disease. Inasmuch as most of the predominant symptoms of splenomegalies are inconstant and variable, the difficulties in obtaining a history can be appreciated.

On September 2, 1923, a patient fitting fairly well into this picture presented himself for advice relative to a large tumor in the left side of his belly. The man was employed as a railway mail clerk. He was fifty years of age and had never been seriously sick. In December, 1922, he suffered an attack of grippe and was sick for three weeks, but did not quit work.

During January, 1923, he suffered with a severe pain in his back. This pain extended from his shoulders to his buttocks and was constant. It was most severe from 8 p. m. to 2 a. m. and robbed him of his sleep. Frequently he was compelled to walk the floor to get relief. The pain lasted for six months. He was treated for rheumatism. The pain gradually ceased in its severity and then disappeared entirely. His relief from pain, however, was of short duration. A pain in the pit of his stomach manifested itself in June and lasted for about six weeks

*Presented at the meeting of the Southern Surgical Association, December, 1923.

when it shifted to the left side immediately under the short ribs. The pain was described as severe, heavy and dull in character.

About the middle of June he noticed that his strength was failing and that he was losing in weight. The loss was about forty pounds in six months for his normal weight of 160 pounds. He was being treated for ulcers of the stomach. During his whole period of indisposition he had a good appetite, no digestive disorders and no bowel disturbances. There was, however, a strong tendency toward constipation. His sleep when there was no pain, was good. He kept at work most of the time. During the middle of August he noticed that there was a large swelling in his left side for which he consulted a physician. Electrical treatment was administered. The tumor, however, increased in size so rapidly that the treatment was discontinued and further counsel was sought.

When this patient was seen by me on September 2, 1923, his general appearance was that of a patient convalescing from typhoid fever. His emaciated appearance was in marked contrast to the clear intellect and the bright eyes. His gait gave evidence of a marked systemic weakness. Inasmuch as his appetite was good and his sleep refreshing, he was unable to account for both the loss in weight and the weakness. The color of his skin was sallow with a strongly murky cast, rather akin to a melanoderma. There was nothing unusual about this as he said that it was his normal color. There never was a jaundiced condition. The skin was dry, parchmentlike to the touch. There was no marked suggestive pallor of the mucous surfaces. The tongue was pale with a bright red streak in the centre. At no time was there vomiting of blood nor bleeding from the nose or gums. The Wassermann reaction was negative and the urinary analysis disclosed nothing abnormal.

Desire for water was ever present. He was free from cough and bronchial irritation. Small quantities of sputum were expectorated occasionally. Some of this sputum was examined microscopically with negative result as to tubercle bacilli. No glandular enlargement about neck, axilla or groin. No edema of lower extremities. Examination of abdomen revealed sufficient fluid in the cavity to impart a well marked tenseness to the belly wall. Its presence hindered the examination of the abdominal contents. Nothing could be definitely elicited on the right side. The lower border of the liver could not be outlined. Pressure upon the abdominal wall provoked no muscular defense, neither did it cause pain. On the left side a tumor was readily palpable, clinging closely to the abdominal wall and extending from under the left costal arch down to the iliac crest with its characteristic notched anterior border in juxtaposition to the abdominal midline with its anterior and lower borders distinctly outlined. This tumor could be moved in a diagonal direction upward and backward from right to left with ease. The manipulation was painful. When at rest tenderness on palpation was confined to the upper portion of the tumor only. The tumor did not respond to the movement of the diaphragm. On percussion the note was uniformly dull over the surface and extended as high as the seventh interspace.

That the tumor which filled the greater part of the left abdominal cavity was a hypertrophic spleen could be accepted without doubt. The question now paramount was the grouping of the pathological process.

If we would have accepted the clinical phenomena and physical signs of this case without further aid of a blood examination, the inference could have been made that the condition was a primitive splenomegaly. However, the result of a rectal examination made previous to the blood examination interjected doubt as to whether the splenomegaly in question could be classed in the splenic anemia group. The rectal examination was a digital one and was provocative of excruciating pain whenever the tip of the examining finger came within close proximity of the left iliac fossa. The pain was not caused by any lesion in the rectum, that part of the alimentary tract appearing to be normal. It was a pathology beyond the bowel, the nature of which could not be definitely disclosed on account of the intense pain caused by the examination. From the viewpoint of a diagnosis this pain proved sufficiently persuasive to entertain a change of opinion relative to the etiology of the splenic enlargement and a provisional diagnosis of tuberculosis or possibly a malignancy (sarcoma) of the spleen was made.

The blood examination which showed an almost normal blood picture—red blood cells, 3,500,000; white blood cells, 8,800; hemoglobin, 70 per cent.—only aided in carrying the diagnosis more distant from the splenic anemia group.

Inasmuch as the patient was anxious to be relieved of this tumor which caused discomfort and pain, he was informed that an operation of an exploratory nature only would be undertaken. A left rectus incision about five inches in length was made. The notched border of the spleen immediately presented itself in the wound. The ascitic fluid was of a pale straw color. My objective for the moment was not so much the greatly enlarged spleen as was the site in the left iliac fossa which appeared so painful on rectal examination. The condition was readily discovered and proved to be a mass of greatly enlarged lumbar glands. Further exploration disclosed the iliac glands also much enlarged. Following the course of the enlarged lumbar glands upward a veritable roll of enlarged glands could be traced toward the diaphragm. Many of these glands were as large as robin's eggs. They were firm, the blood-vessels about them being markedly injected, distinctly revealing anastomotic branches that normally would have been invisible. The lymphatic glands on the under surface of the liver, especially those surrounding the gallbladder, were enlarged and easily palpable. The glands occupying the hilum of the spleen were equal in size to those of the liver and readily demonstrated. The mesenteric glands could be promptly recognized and were all greatly enlarged.

The portion of small intestine which presented in the wound upon retraction of the spleen was found distended with gas, the walls of the gut being almost translucent. The mesenteric base appeared thickened, showing increased vascularization. Upon pressure and rolling the bowel between the fingers no irregularities indicative of ulceration could be detected. Here and there upon the bowel surface were deposits of cheesy matter, some as large as a grain

of wheat. Microscopic examination of these cheesy deposits disclosed them to be semifat and colloid-like material.

Examination of the liver revealed a change from the normal deep brown color to a lighter brown. The sharp anterior border was obliterated and retracted considerably from the lower border of the ribs. Instead of the sharp border there was a well rounded thickened surface which gave the appearance of the organ having rotated. Its consistency appeared normal to the touch. The gallbladder, whose walls felt thickened, was small. It was filled with bile which was easily expressed. The spleen readily filled the greater part of the left side of the abdominal cavity and appropriated the space from the dome of the diaphragm to the crest of the ilium and from the spinal column to the midabdominal line. Its artery was of enormous size and appeared as though it might be a half inch in diameter. The temptation to ligate the vessel was great. In passing the hand over the surface of the spleen adhesions of the cobweb variety were found to envelop the whole organ. Adhesions of a vicious nature were not demonstrable and ablation of the organ could have been accomplished without difficulty.

The surface of the spleen was smooth and through its perceptibly thickened capsule presented a mottled appearance, i. e., there were scattered upon its normally dark purple colored surface numerous small irregular light brown (almost white) patches. These light brown areas were interpreted as resulting from infarctions. The consistency of the organ appeared considerably more firm than normal which was attributed to the existing general hyperplasia. Firm but gentle pressure imparted the sensation of numerous small kernels imbedded in its substance immediately under the capsule. The peritoneum was normal in appearance and did not give evidence of correlation with the existing morbid processes.

The gross pathological lesions in the abdominal cavity were sufficiently clear to establish a diagnosis of tuberculous disease of the spleen. It must be regetted that a wedgeshaped piece of tissue was not removed from the organ to obtain a microscopical verification. It was not done for certain reasons. This verification would have been desirable inasmuch as a diagnosis of a possible sarcoma had also been made.

Sarcoma of the spleen, both primary and secondary, is rare. However the clinical manifestation of rapid growth, much loss of bodily weight in a comparatively short time (three months), together with the radiating pain, tenderness and the presence of ascites, justified the inclusion of malignancy.

It was the pain the rectal examination induced which suggested a possible malignancy of secondary origin. However the gross appearance of the organ negatived any further reason for such an assumption. The organ lacked the general appearance of a sarcomatous process, prominent in which are usually nodules which project more or less from the surface of the enlarged organ. Such nodules were not present. The pathological picture fitted well into a tuberculous disease and grossly was accepted as such. In this I am pleased to say that I received the support of several physicians present. A matter remained to be solved and it was with a feeling of chagrin that it could not be accomplished during the exploratory examination. It was this: Was the existing splenomegalia of primary or secondary origin? From the history a vague inference could be made that a tuberculous infection might be active in the intestinal tract. This of course is more apparent now since the abdominal pathology has been disclosed. At no time, however, was there a definite intestinal disturbance which gave evidence of an existing lesion. The only evidence of any lesion that might be associated with the intestines was the pain caused by rectal examination. It was this pain which prompted the removal of the splenic tumor from the splenic anemia group.

A spleen must attain quite a large size before it can be discovered by the patient. From this it might be assumed that the organ was in an infected condition long before its size was recognized, and was active in disseminating toxic products to the liver and abdominal lymph glands. On the other hand it can be reasoned that tuberculosis of the spleen as a primary infection is admittedly rare and that the toxic agents were previously harbored in the intestinal tract. The problem for me is a difficult one to solve in this case.

The spleen of this patient was not removed. The associated pathology negatived any thought of removal. With its removal it might have been possible to inhibit further damage to the liver cells. I doubt very much, however, if the condition of the abdominal lymphatic glands could have been favorably influenced. In not removing the spleen the hope was entertained that enough of healthy parenchyma was left to carry on a certain amount of resistance against general infection, a faculty accredited this organ, thereby giving a better chance for longer life to this patient than could possibly be offered with a splenectomy. The patient was in the hospital three weeks. At no time were there any untoward symptoms. The course of his convalescence from the operative measure was apyretic, the temperature ranging from 97.2° F. to 99° F. with a pulse rate of 68 to 96.

In connection with the convalescence I may say that twelve days after the operation, the patient had a violent attack of coughing which caused the wound to burst open. When I saw him two hours later the spleen again presented in the wound. The organ appeared somewhat smaller, possibly due to the contraction of its muscular and elastic fibres. The surface of the spleen was covered with a white fibrinous deposit. There was little fluid in the abdominal cavity and the dressing was but slightly moist. The abdominal wound was again sutured and healed by primary union.

The patient's condition eight weeks after the operation was considerably better than before operation. He was entirely free from pain, felt much stronger, and had gained five pounds. His appetite was good, his sleep refreshing and he wished to return to work. There appeared to be a small amount of fluid present in the abdomen. The spleen had receded to a perceptible degree, so much so that the breadth of a hand could be easily placed between the lower border and the crest of the ilium. What the future will have in store for the patient will be of interest.

Anaphylaxis: Development and Modern Conception in Its Relation to Clinical Medicine

HENRY M. RAY, M.D.,

Pittsburgh, Pa.

The growing importance that the phenomenon of anaphylaxis has acquired the past few years in its application to internal medicine has not only yielded magnificent though limited results but it has also opened up a field rich in interest and future possibilities. The fascination which the subject has always had for the laboratory worker is responsible for the massive accumulation of experimental data to which can be attributed the growing interest in the subject on the part of clinicians and specialists. The history of medicine presents many examples of acute and penetrating speculations which left an astonishingly shallow impression on the medical minds of the day simply because they were unsupported by experimental data. Thus it was that when Hericourt, Richet and Portier discovered in 1902 that a dog which had received twelve days previously a harmless dose of actinocongestin became so sensitive to the effect of this substance that a subsequent injection of a dose far smaller than the lethal dose for a normal dog produced violent death, those who heard of the remarkable phenomenon labeled it as a physiological process which would scarcely interest the bacteriologist or clinician. All doubt as to the exceptional nature of the phenomenon was removed when Arthus, Otto and later Rosenau and Anderson demonstrated that a substance as harmless as horse serum was capable of setting up symptoms of anaphylaxis.

Ordinarily, injection and reinjection of an animal with an antigenic substance results in progressive increase in antibodies which ultimately induce a high degree of immunity. Under certain circumstances, however, a second injection is followed by severe and even fatal symptoms, indicating that instead of being immune the animal is hypersusceptible to the effects of the antigenic substance; indeed, an exact antithesis to immunity which means "with resistance to infection" and hence the term "anaphylaxis without protection" where actually the rules of immunity "are standing on their heads" as Besredka remarked.

Anaphylaxis, in the limited meaning of the term, designates the train of phenomena which follows the introduction of foreign protein into man or animal. While the first injection of the protein in itself produces no symptoms it serves to alter the power of reaction on the part of the body cells by rendering them unusually sensitive to this or closely related proteins. On the basis of this and the fact that many of us have come to regard the state of hypersensitivity in the light of a step necessary to attain the condition of immunity, it appears that the term coined by Richet "anaphylaxis" or "against protection" is a misnomer and that the word allergy introduced by Von Pirquet (1902) and meaning "altered reactivity" more appropriately describes the condition.

Following the observation of Von Pirquet, a great deal of work was done on the subject by a number of investigators, more particularly Arthus, Theobold Smith, Otto, Anderson and Rosenau. The researches of the last two, besides confirming the observations of the previous workers, brought out many valuable facts. They showed conclusively that sensitization was accomplished by extremely small doses varying from one one millionth to one c. c.; they proved that the hypersusceptibility was transmissible from mother to offspring and that such anaphylaxis has no reference to the condition of the father and is not transmitted by the milk. They demonstrated that anaphylaxis was specific and together with Vaughan, Wheeler, and Nicolle, they showed that the reaction was by no means limited to animal sera, but was elicited by proteins in general, peptone, egg albumen, milk, extract of peas and bacterial extracts. Another important achievement was the demonstration of the fact that the hypersusceptible state could be passively transferred to normal animals by injecting them with the serum of anaphylactic animals.

To Rosenau and Amos we owe the demonstration that proteins in a volatile state, as in the exhaled breath of men, when condensed and injected into guineapigs, will sensitize these animals to subsequent injections of human serum. While it is doubtful if the complex protein molecule passes out through the lungs in gaseous form, it more likely exists in colloidal solution. Rosenau was also able by keeping guineapigs in stables with horses, to sensitize them to horse serum. These experiments are of fundamental importance in explaining instances of human anaphylactic phenomena among those sensitive to horse protein, e. g., horse asthma.

Regarding the mechanism of anaphylaxis, the lesions and symptoms are practically the same with all proteins when the conditions of dose and administration are the same. The fact that various species present different pictures with the same protein is best explained on a basis of anatomical and physiological differences. Thus Schultz has shown that serum anaphylaxis is essentially a sensitization of smooth muscle which, during anaphylactic shock, contracts wherever it is present. In the guineapig, this effect is most evident in the bronchi, owing to the peculiar though normal anatomical structure of the mucosa which is so thick as to be thrown into folds which completely obliterate the lumen during the contraction of the smooth muscle, resulting in inspiratory asphyxia. This condition is less marked in dogs and rabbits who have relatively thin mucosa and poverty of smooth muscle, accounting for the lack of respiratory embarrassment during anaphylactic shock in these animals, which show smooth muscle manifestations in the form of vigorous peristalsis, vomiting and involuntary emptying of the bladder. In man, the definite urticarial and other rashes and the inspiratory asthma of those pecu-

liarly susceptible to a protein due to encroachment upon the bronchial space analogous to the condition occurring in guineapigs, the diarrhea and the secondary drop in blood pressure, all point to a similar action upon the smooth muscle. Herein we can also find an explanation of the pharmacological action of atropine, sedatives and anesthetics in alleviating or masking the symptoms of acute anaphylaxis.

Briefly, anaphylaxis in the human manifests itself in a severe fall in blood pressure and temperature, leucopenia, local and general eosinophilia, diminution of complement, reduced coagulability of the blood and according to Pfeiffer the presence of poisonous substance in the urine.

Passive anaphylaxis affords an interesting phase in the study of this subject and is illustrated by the maternal transmission of hypersusceptibility to the offspring, a fact I have previously alluded to. Rosenau, Anderson and others have demonstrated that injection of normal animals with serum from sensitized animals, renders the recipient hypersensitive so that an injection of the same protein elicits all the manifestations of intoxication. Besredka showed that the injection of animals with serum from patients hypersensitive to certain foods, renders these animals anaphylactic to an injection of the food in question.

Antianaphylaxis is a term first applied to designate the condition of insensibility to further injection of protein. It may follow recovery from anaphylaxis or it may be artificially produced by repeated injections of small doses of protein during the incubation period, that is, before sensitization is complete. As a rule, such an artificially induced refractory state is only temporary since the animal becomes sensitive again after three weeks. The subject of antianaphylaxis is of great importance from its relation to serum therapy, and thus far, no satisfactory method for producing this state in a sensitized person has been devised although the various and partly successful attempts made by different workers to destroy the socalled toxic substances of sera have actually no real bearing on the anaphylactic reaction. In the detection and prevention of serum disease it should be remembered that anaphylactic phenomena can usually be expected to occur if serum is given within a year or so following previous injection. It is important to question persons who experience discomfort when in the neighborhood of animals and it is well to make the simple test of rubbing in a drop of the antitoxin into the scarified skin with a tooth pick, as in vaccinating with cowpox virus; the urticarialike lesion develops usually within fifteen minutes and there are rarely any general symptoms. Some give atropine sulphate, one one hundredth grain, before injecting the serum and repeat the drug at twelve hour intervals in cases where serum has been given within the past year.

The anaphylactic or allergic skin reactions have found their greatest application in the diagnosis of tuberculosis, glanders, typhoid fever and syphilis. Kolmer and others have demonstrated well marked reactions in favus and ringworm. It must be remembered, however, that the skin reactions in these conditions are not always elicited, especially during the acute stages. An interval of time is required for sensitization, so that the greatest diagnostic value of these skin reactions is in chronic infections. The positive anaphylactic skin test is evidence of infection or sensitization to a particular protein and according to more recent work is no index as to the immunity of an individual to a particular infection.

RELATION TO IMMUNITY

One cannot escape being impressed with the close interrelation between anaphylaxis and immunity. It is difficult to reconcile the coexistence of immunity and supersensitiveness in the body at the same time, yet, an animal enters upon the anaphylactic state at the same time that its blood develops those properties which are indicative of the state of immunity. Metalnikov has examined this phenomenon and advances a rational explanation. The basis for anaphylactic phenomena is to be found in the increase in cellular sensibility, a widely accepted current view. This increased cellular sensitivity is in the nature of a protective phenomenon, the cells, once damaged by a particular agent, react on a subsequent exposure to the same influence, with an accelerated response. The presence of increased cellular activity is proved by experiments in which capillary tubes filled with the antigen in question are introduced into the peritoneal cavity and beneath the skin of animals which have been sensitized to the same antigen some weeks previously and are therefore sensitized from the anaphylactic point of view and have developed immunity. Removal of these tubes twelve hours later reveals that in the sensitized animal the tubes have accumulated a large number of leucocytes while in the control normal animals the leucocytic emigration is at a minimum. This is of course a phagocytic phenomenon and expresses itself in the clinical demonstration of anaphylaxis in the Arthus phenomenon, where the local application of an antigenic substance results in a pronounced reaction and accumulation of wandering cells at the site of injection. Upon the assumption of the recognition of cellular activity in these phenomena, the findings of Roux and Besredka of their inhibition of anaphylactic shock with anesthetics and narcotics, are readily explained.

In the absence of a better explanation of anaphylaxis we must agree with Metalnikov that anaphylaxis and immunity are but different phases of the same phenomenon; both processes have in common a purposeful attempt to protect. With a subsequent exposure to the antigenic substance, be it infectious, chemical or foreign protein, the primary result is obviously a resistance and hence protection conferred by immunity; however, when the second exposure is of massive intensity as, for example, that obtained under the artificial circumstances in experiments on anaphylaxis, the previously prepared cells respond with overwhelming violence in the production of a profound and violent reaction, the anaphylactic response, dependent not on hypersensitiveness but really an expression of an increased protective reaction.

RELATION TO NONSPECIFIC THERAPY

Another interesting phase of anaphylaxis is its study in relation to nonspecific or socalled foreign protein therapy. Reports from all over the world indicate that remarkable results have been obtained with this type of therapy, particularly in infectious

processes, notably in arthritis and respiratory affections. While, strictly speaking, anaphylaxis implies a specific hypersensitivity, specific as regards the substance introduced into the body, one must certainly view the marked reactions obtained in nonspecific therapy in the light of an anaphylactic phenomenon, where the body fluids and cells are altered in their response to an infectious agent or to the products of inflammation. So it is that the basis of nonspecific therapeusis from an immunological viewpoint has for its object an alteration of the reaction of the organism to the etiological agent rather than an attempt to influence the causative factor of the inflammatory process directly. The interrelation is further emphasized by the established fact that the symptoms of allergy may often be temporarily relieved by the use of nonspecific protein therapy in cases where one is unsuccessful in finding the specific allergin. Nonspecific therapy employs the anaphylactic reaction as a method of stimulation of all the forces of cellular and humoral resistance. It is difficult to conceive that the good results obtained in infectious diseases from nonspecific therapy are attributable solely to the leucocytosis and the proteolytic ferment which the leucocytes liberate. The profound alteration in cellular reactivity is so little understood that it is useless to attempt an explanation of the factors involved in nonspecific treatment until we know more about the mechanism of anaphylaxis.

CLINICAL CONSIDERATIONS

Evidence that a great variety of clinical manifestations have an allergic basis is rapidly accumulating in the literature. The relation of specific hypersensitivity in dermatological disorders and respiratory affections, particularly asthma, has already been firmly established on both experimental and therapeutic bases. Of particular interest are the cases of gastrointestinal allergy which may simulate any of the organic gastrointestinal disorders, not excluding ulcer. It is in these latter cases that it is often necessary to perform the cutaneous tests with a large number of materials before the offending substance can be found. Occasionally, an individual reacts to three, four or even six substances, making it necessary to eliminate one at a time so that the offending substance can be isolated by the process of elimination. It sometimes happens that the toxic substance is found to be a common and important dietary constituent, such as, for example, milk or potatoes, and it is in these cases that one experiences the greatest difficulty in attempting the process of detoxication. Occasionally it is impossible to bring about desensitization in spite of anything one may do. The case of a boy exceedingly sensitive to milk failed to respond to parenteral and alimentary attempts at desensitization. The alimentary tolerance ceased with eight drops of a milk solution of one in one hundred. An interesting case in a young woman of hypersusceptibility to milk, manifesting itself in an attack of asthma and urticaria, is reported by Clarke and Meyer who attempted hyposensitization with little success.

So large a number of hypersusceptible individuals give a history of the existence of a similar state in some other member of the family that the element of an inherited constitutional susceptibility cannot be ignored. My own work on rabbits has convinced me that sensitization passively conferred by the injection of the serum of another rabbit which has been actively sensitized to egg albumen, is only relative and temporary. This further supports the element of heredity in view of the fact that hypersensitivity as is ordinarily met with in the human is more or less a permanent condition.

The symptoms of allergy are numerous and are referable to practically every organ in the body. The most common symptoms are those which arise from the mucous surfaces, namely, the respiratory tract and conjunctivæ, which are more likely to be exposed to foreign substances in the environment, and also the gastrointestinal tract. The dermatological manifestations in the form of urticaria, angioneurotic edema, eczema and erythema are next in frequency. In addition to these there may occur neurological disorders, headache, arthritis, hypotension and urinary symptoms. All of these symptoms may be modified or aggravated by associated organic disease, reflex disorders, nonspecific irritants and coexisting infection.

It is important to keep in mind the possibility of allergy in all cases which fail to show an organic basis for their symptomology after careful investigation. Closer attention to the possibilities of sensitizations would undoubtedly save many patients from being placed in the psychoneurotic group. The cutaneous tests are easily performed and a large number of substances can be tried on the skin of the back in a short period of time. In addition, the use of the intradermal and ophthalmic tests are useful and often indispensable. The cutaneous test is simpler to perform than the intradermal, which is more likely to yield false positive reactions but may be more reliable in certain cases of food allergy where the simple dermal tests are unsatisfactory. It is advisable to control and verify one's conclusions by clinical tests of inhalation, ingestion or change of environment, according to which measure is indicated. When the desired substance is not marketed in the usual form of paste or powder, it is a relatively simple matter to inoculate the substance directly, using decinormal sodium hydrate as a solvent.

Close attention to details in the history with special inquiry into the occupational environment is helpful in giving a clue to the offending substance, thereby eliminating the necessity in many instances of having to resort to testing out a multitude of substances. For example, it is not uncommon for parents in relating the histories of an epileptic child, to date the onset of symptoms to a time when a new substance was introduced into the dietary as, for example, cow's milk. Neurologists have been able to control or even cure a limited number of epileptics who show definitely an anaphylactic basis.

IMPORTANCE IN INDUSTRY

In the last few years, attention has been directed to the importance of organic dust in the industries particularly in its bearing on the etiology of asthma, perennial hay fever, and obscure gastrointestinal disorders. If we consider the small proportion of individuals engaged in the lead and paint industries who present manifestations of poisoning and the large

number of workers who can continue in the same line of work for years with relative immunity, the conclusion that the underlying basis is allergic in nature is inevitable. The recent work of Bernton in occupational sensitization to castor bean, Walker's case of a jewel polisher who became sensitized to boxwood dust, Peshkin's case of a pharmacist in whom bronchial asthma developed because of an acquired sensitiveness to powdered ipecac, Rackemann's case of a coffee worker with a positive skin reaction to coffee dust and eight professional bakers with positive skin reactions to wheat proteins, and my own observation of a soap salesman who gave a marked skin reaction to soap powder, are typical examples of sensitization to organic dust in the industries.

COMMENT AND SUMMARY

It has not been my intention in this paper to employ the terms anaphylaxis and allergy in a synonymous sense. I have endeavored to replace the term anaphylaxis by allergy wherever the subject under discussion was not in the true sense an anaphylactic phenomenon. While I have attempted to show the close interrelation of anaphylaxis to immunity, nonspecific therapy and the various food and drug poisonings, the evidence that these are truly anaphylactic in nature is as yet sufficiently incomplete to warrant the use and adoption of an alternative name, as allergy.

It is evident from this historical and developmental sketch of anaphylaxis that clinically great strides have been made in a subject of which the explanation still remains obscure, in spite of the tremendous amount of devoted research on the part of laboratory workers throughout the world. The poverty of positive findings in the morbid histology of this subject is almost discouraging. In the histological examination of the organs of forty-two rabbits and twelve guineapigs dead from anaphylactic shock, I have been able to find nothing more than generalized congestion particularly of the liver capillaries with marked granular degeneration and swelling of the hepatic parenchyma and to a smaller extent of the adrenals. Broughton has found changes in the small arteries of the viscera characterized by endothelial degeneration, edema and fissuring of intima and media and splitting of the internal elastic lamina. The disappointment of the pathologist is shared by the bacteriologist and immunologist. The trend of immunological research seems to have taken the path of physical chemistry particularly in its relation to colloids. This course is justifiable when it is considered that a sudden change in the equilibrium of certain colloidal complexes of blood plasma is sufficient to produce all the phenomena of anaphylaxis. An example of this is seen in the chill which follows exposure to cold and precedes hemoglobinemia. The socalled hemoclastic crises with the accompanying fall of blood pressure, leucopenia, refraction of blood platelets and especially the changes in coagulability, suggest strongly an alteration of the colloidal complexes of the plasma. It appears that the vegetative nervous system is very sensitive to chemical changes of the plasma. Experiments in shock showing cardiac inhibition, disturbances of conduction, the effect of cutting the vagi and the action of atropine, tend to show the relative instability of the vegetative nervous system as a result of its susceptibility to colloidal alteration of the body fluids. Thus from the viewpoint of the nervous system allergy may be regarded as the specific sensitivity of the organism.

Considering our present state of knowledge of the entire subject and its vast clinical importance it is premature if not unfair to relegate its development to any single branch of laboratory research. The difficulties are great enough to require the combined and coordinated investigations of all branches of laboratory endeavor. Thus we will more closely approach an explanation of the mechanism of anaphylaxis, the elucidation of which will not only explain the closely allied conditions of serum sickness and infection in its relation to so called bacterial anaphylaxis but promises also to illuminate the factors involved in immunity, nonspecific therapy and the large number of food and drug allergies which are confronting the clinicians of today.

A complete bibliography will appear in the author's reprints.

A Case of Rat Bite Fever in Hawaii

JAMES ALBERT MORGAN, M.D.,
Honolulu, T. H.

Rat bite fever, sodoku or sokiosa (Japanese), is an acute febrile disease caused by a spirochete, Leptospira Morsus-Muris, inoculated into man by the bite of an infected rat, causing a local disturbance at the site of infection, followed by a general fever, with a tendency to relapse and in some cases a cutaneous rash (Manson-Bahr).

This comparatively rare disease has been known to Japanese physicians for a long time. Futaka, Taniguchi, Takaki and Osumi demonstrated long slender spirochetes in the lymphatic glands from the tenth to the thirteenth day of the illness; later they found similar, though shorter and stouter, organisms in the blood stream, these latter now recognized as being the younger forms of the organism. Kaneko and Okuda confirmed this work later on. The incubation period varies from one to sixty days, with an average of ten days, during which time the wound heals. The cicatrix usually becomes inflamed and surrounded by blebs and even necrosis, although it was not so in this case. The lymphatics draining the area become tender and swollen. Eosinophilia and a moderate leucocytosis are usually present during the paroxysm but it did not occur in this case. About three per cent. of the house rats in Japan are natural carriers of the disease. The rat in this case was a

Rattus Alexandrinus, or tree rat, which is quite common in Hawaii at both sea level and in the mountains about dwellings. Salvarsan has proved a specific for this disease.

While tropical medicine is not exactly within the sphere of the rhinologist, the following case having occurred in a member of my family, I feel that a report of it should be on record:

Case.—The patient, a male child, just past his third year, was bitten by a rat on August 23, 1923. The older children, having caught the rat in the hollow of a tree, had tied a string about one hind leg. The patient put his right foot too near the rat and was promptly bitten on the tip of the great toe. The punctures were no larger than two pinheads and bled profusely. The wounds were cauterized and healed by first intention. As there were no further developments the episode was practically forgotten.

On September 19th the child became feverish, the fever continuing for about eight hours. The following day the child's body and extremities were covered by an urticarial rash. There was considerable itching for a few hours and by the following day the rash had entirely disappeared. At the time the condition was thought to be a slight indigestion, as fermentation in the gastrointestinal tract was noted.

On September 23rd an area of redness and induration appeared in the right inguinal region. The deeper glands seemed to be involved and the patient complained of pain when attempting to walk. At this time there was fever for about eight hours. At the same time there appeared several erythematous areas on the same leg below the knee and two spots over the left lumbar region. After profuse sweating the temperature dropped to normal, but the glandular enlargement and the spots persisted unchanged.

On October 1st, after four days without any temperature and only slight tenderness in the right inguinal region, there was another attack of fever. The temperature rose rather sharply at 10 a. m. and continued high until 9 p. m. A severe convulsion occurred just before the temperature began to fall. During the remainder of the night the fever was intermittent in character reaching the normal by daylight. The following day there was marked tenderness and induration in the right inguinal glands and the color was of a purplish hue. The spots on the legs and back had a similar color and were gradually spreading, two large ones coalescing. Even at this time the true cause was unsuspected, as the condition was not known to the physicians of this section. During the subsequent four days, outside of the glandular tenderness and induration and appearance of more spots, the patient appeared normal, although rather fretful.

On October 5th another attack of fever occurred which lasted from 3 p. m. until 3 a. m. During this attack the fever was more intermittent in character, with intervals of from one half to one hour of practically being normal. Profuse sweating usually followed each attack. During this attack the involved inguinal region seemed much less tender but the spots had become larger and much more numerous. At this time and between attacks numerous blood smears were taken with negative results.

On October 9th, the fever returned about 3 p. m. and continued until 6 a. m. At this time the right inguinal region showed practically nothing except a slight discoloration of the skin. The erythematous spots were as large as the palm of the hand, and of deep purplish red color around the edges, paling to a dirty yellow in the centre. One large spot was at the base of the neck on the left side and another covered the entire left deltoid region. Smaller ones were noted at the right corner of the mouth and numerous others of various sizes were seen on the back of the arms and legs.

At this time, after consultation, the case was considered one of rat bite fever, although the organism had not been demonstrated. Sulpharsphenamine, 0.2 gm., dissolved in 0.8 c. c. distilled water, was injected deeply into the right buttock. About one hour after the injection the temperature mounted a little higher and the spots became much swollen and indurated. The patient awoke frequently and complained of pain in the region of the spots. The temperature dropped to normal about 6 a. m. During the subsequent day the temperature remained elevated for about one degree, until evening. The erythematous areas continued tender and somewhat swollen during the next two days and gradually faded out. As the spots disappeared there appeared a puffiness of the left hand and right foot, as well as under the eyes. There was no pitting on pressure. Uranalysis during and between the attacks revealed nothing abnormal. Triple phosphates were excessive following the fever. During the subsequent four days the puffiness disappeared. No further recurrence was noted.

During the two weeks, until October 23rd, the patient seemed normal, when there was a rise of temperature of twelve hours' duration. On October 26th there appeared an erythematous spot on the chin. This spot was similar to those that appeared during the previous attacks of intermittent fever. During the next three days this spot extended upward about the right corner of the mouth and involved the upper lip. The color became of a deeper reddish purple fading as before into a central soiled yellow.

On October 26th, at 6 p. m., there was a sharp rise of temperature to 104°, with no other symptoms except increased redness and tenderness of the spot on the chin. At 8 p. m. 0.2 gm. sulpharsphenamine dissolved in 0.8 c. c. distilled water was injected deeply into the left buttock. Following the injection the temperature increased as in the previous attack and dropped with profuse sweating. During the remainder of the night the temperature was intermittent as before. By ten o'clock the following morning the body was covered with a fine urticarial rash which itched considerably. The urticaria disappeared by evening and the spot on the chin faded during the next two days. Smears taken from the centre of the spots during the fifth attack showed some short, thick spirochetes in a number of fields, but these were not sufficiently typical to differentiate them from artifacts.

November 14th. For three days there had been a slight rise of temperature each afternoon. Today at about three in the afternoon there was a rapid

rise in temperature to 102° by axilla and the fever remained high until two in the morning. At six p. m. 0.3 gm. of sulpharsphenamine, dissolved in 0.9 c. c. distilled water, was injected into the right buttock.

Following this injection the temperature was higher with shorter intervals of lower temperature and sweating. By one in the morning the patient was quite delirious, chewing the corner of the sheet and picking at the bed clothing and striking his head with his hands. After about one hour of this delirium, the temperature dropped to normal with profuse perspiring. During this attack there were no spots observed.

November 19th. At this time a few erythematous spots had appeared on the legs posteriorly. There were no other symptoms. It was decided not to wait for another attack but give two more injections of the specific drug at five day intervals; 3.0 gm. sulpharsphenamine, dissolved in 0.9 c. c. distilled water, was injected deeply into the buttock at 7 p. m. The only reaction was a moderate siderosis during the night and restlessness. The spots on the legs had entirely disappeared by noon of the following day.

November 24th. The final dose of sulpharsphenamine, 0.3 gm., was injected in order still further to assure a cure. The only reaction was a profuse sweating as before for a few hours. Before and following each injection a complete uranalysis was done with negative results. Practically two months having elapsed since the last attack of fever it was considered cured.

Very little information concerning this comparatively rare condition could be found in the available literature. Some authors advised intravenous injections of neosalvarsan, only one dose being necessary. Others advised arsenic by mouth and still others intramuscular injections. The more conservative treatment was decided upon and the end results were no doubt as satisfactory as though more radical measures had been employed. There was practically no local reaction at the site of the injections in the buttocks.

ALEXANDER BUILDING.

Intracutaneous Vaccination Against Smallpox*

J. H. GETTINGER, M.D.,
New York,
Associate Visiting Physician, Department Pediatrics, Bronx Hospital

There are many landmarks among the ruins of empiricism in ancient medicine which lead one to believe that many of the early medical scientists recognized the infectious nature of certain diseases and the conferring immunity that an attack of some carried with them. But it was through the ardent efforts and the masterful experiments of Edward Jenner on smallpox that immunology reached its scientific culmination. And today, when we peruse the literature upon infection and immunity which has since been added to the archives of medical information, we are struck with awe and amazement by its vastness, and we look askant at the mighty strides this subject has made within recent years.

Since the introduction of vaccination by Jenner, many experimental observations were made upon the various methods and sites of vaccination. Some made the scarification upon the ankle, others, on the calf of the leg, others still preferred the thigh or the inner side of the arm. In fact, almost the entire anatomical topography has been explored and traversed in search of a favorable and suitable site, so that the inevitable scar might not stand out in such a prominent discord with cosmetic harmony. However, most of these experimenters confined themselves mainly to the old and unique method of cutaneous vaccination by scarification, changing the locality and habitation of the scar but not its objectionable hideousness. Even Pirquet, in his exhaustive studies on this subject, limited his field of observations to cutaneous reactions.

At length, however, the question was raised, whether the superficial skin and the specific process manifested through scarification created the desired immunity against smallpox; or could the same immunological results be obtained by using other means of conveying the vaccine into the system. This consideration was prompted by an anxious desire to obviate the usual injuries to the skin with the resultant scar formation, as well as to mitigate constitutional reactions and to avoid possible secondary infection. It was likewise of theoretical interest to see how the intracutaneous vaccination, the nearest method to cutaneous vaccination, worked on man.

By the experiments that Chauvsau started in 1866 and which he carried out on various species of animals and on man, it was proved that subcutaneous and intravenous injections of vaccine produced immunity against cutaneous revaccination. But in these subcutaneous injections, quite as much as in the old methods of inoculation, swelling and inflammation were often observed at the site of injection, and in some cases, a typical vaccine exanthem appeared. Almost simultaneously Fröhlich obtained practically the same results from experiments carried out upon cows. These findings were in agreement with those resulting from experimentations upon various species of animals by Senft, Casagrandi, Strauss, Chambon, Menard, Beclere, Calmette, Guerin, Tedeschi, Janson (also upon children), R. Kraus and Volk, who obtained positive vaccine reaction by this method.

The last works on the subject of vaccination and its practical application appeared in the years 1906-1910 by Nobl and Knopflemacher. The latter worked out completely, from a clinical point of view, the subcutaneous application of pox vaccina-

*Read before Bronx Hospital Clinical Society, May 14, 1923.

tion, similar to Pirquet's work on cutaneous methods. The principal results of Knopfelmacher's work were that complete immunity against variola is obtained in man by the subcutaneous injection of one c.c. of lymph in a dilution of 1:200. The symptoms of successful vaccination appearing at the place of injection between the tenth and fourteenth days were a circumscribed infiltration and erythema, the erythema disappearing in a few days while the infiltration remained several weeks.

In 1910 a work by Novotny and Schick appeared on vaccine inoculation of the rabbit by intracutaneous injection of cowpox lymph; proving that virulent lymph, when injected intracutaneously into the shaved skin of the rabbit, always gives positive results. The application of this intracutaneous method of injection of vaccine in man was not dwelt upon. We are, nevertheless, led to infer that intracutaneous vaccination would, with the proper technic show the same reaction on human subjects, eliminating the disadvantages of scarification, and lend itself to better observations than the deep process of the subcutaneous method.

The experiments of Leiner and Kundratitz show conclusively that they succeded, by the intracutaneous vaccination of cowpox lymph, in creating an immunity against cowpox virus, and in producing a typical reaction which differs from the usual reaction following cutaneous vaccination, this reaction being, moreover, much easier to observe than that which takes place following subcutaneous inoculation. They employed lymph supplied by the State Department in dilution of 1:3. This lymph was used as it was received or in dilutions up to 1:100. The diluent was either sterile physiological salt solution or plain sterile water. For general practice it is not necessary to have an exact dilution. In order to avoid the vaccine's coming in contact with the skin about the puncture, a separate large needle was used to draw the vaccine into the syringe, this needle being then removed and a finer one adjusted. The second needle was inserted 1.5 cm. into the cutis and its point tilted in such a manner that during injection a typical intracutaneous wheal was produced. After the withdrawal of the needle from the skin, the point of puncture was cleansed with tincture of iodine and alcohol.

It is important to carry out these details with precision, for the omission of any precaution might result in cutaneous vaccination at the site of puncture or, if the needle be inserted in the skin too superficially so that the point shows through, it is likely to result in a cutaneous reaction.

Of the fifty children that Leiner and Kundratitz injected intracutaneously, ranging in ages between two and eleven years, thirty-nine showed positive results; that is, a typical intracutaneous reaction with an immunity against any subsequent revaccination. In six patients the process was not completely typical, while in five there was no reaction at all, just as sometimes happens in cases with the usual vaccination.

In order to prove that immunization had been established by intracutaneous vaccination, cutaneous vaccination by scarification was afterward done on these same patients. If the cutaneous vaccination was performed at the beginning of intracutaneous reaction or about two days later, the result of the cutaneous vaccination was entirely negative. If the cutaneous vaccination was done fourteen days after the intracutaneous reaction had set in, some cases showed no reaction, while others showed a slight red nodule after the eighth or tenth day. This nodule underwent a retrogressive metamorphosis after two days.

The typical reaction of intracutaneous vaccination may be described as follows: After twenty-four hours, there appears at the site of injection an erythema about six to ten mm. in diameter, paler in color towards the periphery, with a distinct infiltration slightly raised above the skin level in the centre. The erythema lasts but a few days, but the infiltration spreads to a larger area after ten to fourteen days, becoming distinctly limited in the subcutis and movable on the base, while the skin above is not movable: there is a slight redness over the infiltration. These transitional changes last about three weeks, the infiltration becoming smaller, the skin over it going through a fading discoloration. Finally the infiltration disappears and the skin resumes its usual color. There is little or no temperature during the entire period of reaction. The pathology of the reaction in both the cutaneous and intracutaneous vaccination is probably the same, namely, exudation, proliferation and degeneration, the only difference being that in the intracutaneous vaccination, the prolifieration predominates.

In reviewing the whole process of vaccination in the intracutaneous method, we can distinguish two reactions. The first reaches its height within twenty-four to forty-eight hours after injection; the second takes place between the tenth and the fourteenth day after the complete disappearance of the first reaction and lasts about three to four weeks. It is this second reaction that confers the immunity.

Since the publication of Leiner and Kundratitz's article, this method has been tried in a number of clinics and in private practice with uniformly gratifying results. Curt Frankenstein reported that it had proved especially valuable in the vaccination of infants, and published on account of the treatment of sixty very young infants by intracutaneous vaccination. The first reaction expressed itself in a firm, sharply circumscribed infiltrate with an intensive central reddening which was markedly enlarged by the fourth or fifth day. This area was hard, very sensitive to pressure, and movable on the substrate. By the fifth day there was enlargement of the axillary glands but the reaction began to subside by the ninth day following injection. In only one case was there softening of the infiltrate; in another, a small pustule formed at the site of injection, leaving a scarcely visible scar after healing.

Twyman, of Missouri, employed intradermic vaccination upon six hundred and twenty patients, three hundred and ninety-seven of whom had not been previously inoculated by any method. On twenty-three persons, who said they had had smallpox, the intradermic vaccination "took." The typical fully developed reaction, following the employment of this method, is an umbilicated pustule which appears about four days after the injection. Most of the cases showed a slight scar, the size of the original wheal raised at the time of the primary injection.

Twyman regards this method as vastly superior to the old scarification inoculation but his results do not compare very favorably with those obtained by Leiner and Kundratitz and others who have adopted their technic.

The confusion often existing in the minds of many physicians between the endermic and intradermal method of inoculation, is noted by Fred S. Spearman, of Colorado, when describing the technic which he employed for subcutaneous injection as a substitute for vaccination by scarification, which is substantially the same as that used abroad. Among thousands of soldiers and children, vaccinated by this method, he had no cases of infection, and the majority of the patients experienced little or no inconvenience. He cites, as special advantages of this method, the rapidity with which a large number may be vaccinated, the avoidance of external scars, and its adaptation to the treatment of children or the insane and feeble minded, who are likely to disturb the healing of the usual vaccination "sore."

At the clinic of the Bronx Hospital, we have practically carried out the technic of Leiner and Kundratitz, using for each case the contents of two capillary tubes of vaccine supplied by the Board of Health. The vaccine is emptied into the barrel of a syringe to which is added ten drops of sterile water. The piston is then inserted and the whole mixture vigorously shaken to disolve all particles and then injected into the skin of the left arm on the usual site.

In conclusion, we can say that vaccination lends itself to three methods of procedure:

1. Cutaneous vaccination by scarification.
2. Subcutaneous vaccination.
3. Intracutaneous vaccination.

Of all the enumerated methods, the intracutaneous holds out, in palapable manifestation, the greatest advantages.

1. It does away with the usual ugly scar incident to scarification.
2. It minimizes constitutional reaction.
3. It eliminates the possibility of secondary infection, also the possibility of conveying the virus, by the fingers of the child, from the vaccination into its eyes, a not infrequent sequel to the present form of vaccination.
4. It would induce parents to vaccinate children throughout the year instead of limiting it to the seasonal period of warm weather.
5. There is no doubt that vaccination would become more universal in its adoption, in view of the fact that the staring hideousness of a festering wound would be eliminated.

It is surprising that while medical men have been keenly alive to the improvement in the minutest physiological tests and allergic data, which at best serve only a theoretical interest rather than a clinical usefulness, they have shown an utter indifference to the constructive betterment of one of the first methods which formed the basic principle of immunology. We vaccinate today in the same manner as our predecessors did a century ago; the same needle, the same scarification, the same deforming scar, the same invitation for reinfection; all of which bear the insignia of antiquity. True, that where large groups are to be vaccinated, the old method by scarification might be more expeditious, because of its ease and simplicity; but speed and simplicity should not determine the choice of a method when the outstanding features of another proclaim its superiority. Indeed, every effort should be made to facilitate the adoption of this method which is neither a fad nor a fancy, but a method of substantial practicability whose efficacy has been definitely established by clinical evidence and experimental data.

A uniform dilution could easily be fixed and put up in ampoules in a suitable form for immediate use by the general practitioner. In this way, intracutaneous vaccination would soon gain the preference it deserves and thereby replace an antiquated procedure of many disadvantages.

729 Kelly Street.

Two Cases of Botulism*

WILLIAM A. PINKERTON, M.D.,
AND JOSEPH KROBALSKI, M.D.,
Bayonne, N. J.

On December 30, 1923, Mr. L. and Mrs. H. had dinner at the home of a friend in Plainfield, N. J. There were ten people at the dinner, three of them children. The dinner consisted of fresh chicken, soup, Jell-O, canned squash and icecream. Everyone partook of all the ingredients of the dinner except the squash, which was eaten by only four of the party. Among those four were the two patients and a sister of the female patient. The sister, who resides in New York City, had only a few mild symptoms, according to her physician. On December 31st, the patients began to have malaise, and loss of appetite. That day they had nothing to eat but freshly made soup. The woman became quite ill that night with vomiting and diarrhea. On January 1, 1924, the man also began to vomit and that day both patients complained of weakness, diplopia, blurred vision and vertigo. They were under the care of their family physician until January 3rd, when they were advised to go to the hospital for observation and treatment.

On admission the patients were obstinately constipated but had no vomiting. They complained of weakness, diplopia, difficulty in speech and inability to swallow. The mucous membranes of the mouth and throat were dry and there was a nasal sound to the voice. When they attempted to swallow, they became cyanosed and the fluid regurgitated through

*Read at the clinical conference of the Bayonne Hospital, Bayonne, N. J.

the nose. The pupils were dilated and reacted sluggishly. The man's temperature was subnormal, 97° F., while the woman's was 101.4° F. The pulse and respiration were increased in both cases. Uranalysis showed traces of albumin and fine hyaline casts. The urine was cloudy and of higher specific gravity than normal. The blood count showed a decreased number of erythrocytes and an increased number of leucocytes. The polymorphonuclear count was also slightly increased. On examination, the feces was negative except for numerous gram negative and gram positive bacteria. The diagnosis was botulism.

Treatment consisted of gastric lavage, polyvalent botulinus antitoxin (thirty c. c. intravenously), calomel one quarter grain every fifteen minutes for eight doses followed by magnesium sulphate one ounce two hours later, high colonic irrigations every four hours, milk eight ounces and water sixteen ounces every four hours, and strychnine one sixtieth of a grain every three hours hypodermically. Owing to the extreme dysphagia, the fluids were passed into the stomach by means of the stomach tube, but this caused gagging and cyanosis and had to be discontinued. Murphy drip of glucose and sodium bicarbonate five per cent. was given instead, supplemented by nutrient enemata consisting of one egg, eight ounces of milk, and one half ounce of whiskey given every four hours. Cathartics were given frequently.

On admission the patients were very weak and in rather poor condition. After administration of the antitoxin and thorough cleansing of the gastrointestinal tract, the patients showed some improvement and were much brighter. Four days after admission they were able to swallow a little fluid and the eye symptoms began to clear up. Five days after admission the patients were able to take liquid diet and the nutritive enemata were discontinued. On the seventh day the patients were able to take soft diet. On the thirteenth day, they were allowed to get out of bed, but were still quite weak; and on the sixteenth day, they were discharged. The patient whose symptoms came on later, showed more severe symptoms and made slower progress to recovery.

Stool cultures were made under strict anaerobic conditions on meat infusion broth and glucose agar. A suspension of the stool in normal saline was heated to 60° C. for one hour and then the cultures were inoculated and incubated at 37.5° C. for ten days. Smears were made and stained with gram stain. The culture showed formation of much gas of a very disagreeable odor. The stained smears showed Bacillus botulinus with spores. This finding was corroborated by the United States Public Health Service. Guineapig inoculation with the supernatant fluid of the centrifugalized meat infusion broth cultures were made and control animals were inoculated with sterile meat infusion broth.

The first inoculation consisted of one and a half c. c. of culture and a corresponding amount of meat infusion broth for the controls. After twenty-four hours the guineapig which was inoculated with the culture showed some malaise, while the other showed no reaction. These animals were reinoculated with two and a half c. c. of culture and control broth respectively as before. At the end of seven hours, the experimental animal showed loss of appetite and general weakness. At the end of fifteen hours, there was paralysis of the lower extremities and gradually the entire lower part of the body became paralyzed. The animal took no food and lay motionless even when turned upon its back. Ptosis of the eyelids was also observed. Death occurred in twenty-seven hours; probably from paralysis of the diaphragm. All this time the control animal showed no reaction, the appetite and general activity being normal. Postmortem findings on this guineapig showed the stomach dilated and full of foul gas with a slight amount of partly digested food taken a few hours after the second inoculation. The cecum was also distended with gas and contained a great deal of fecal matter. The heart showed a rightsided congestion, especially of the right auricle. The bloodvessels in all the organs were markedly injected. Sections were made of the heart, lungs, liver, spleen, and kidney. These sections showed degenerative processes in the heart, liver, and spleen. The lungs were congested with blood. The kidney was normal and no organisms were found. Part of the spleen and liver were rubbed with saline solution and incubated overnight at 37.5° C. Cultures from this suspension were made on meat infusion broth under anaerobic conditions and incubated at 37.5° C. for eight days. This culture was centrifugalized and four c. c. of the supernatant liquid was injected into a guineapig. Another four c. c. of this culture was heated at 80° C. for a half hour to inactivate it and was then injected into a second guineapig. A third animal injected with four c. c. of a pure sterile meat infusion broth. Three and a half hours after injection, the animal which was inoculated with the inactivated culture developed convulsions and died. Postmortem examination of this animal showed one large and multiple small abscesses of the liver. These had probably existed before inoculation and were the cause of death. The other two guineapigs were symptomless after forty-eight hours.

DISCUSSION

Most of the workers on this subject have found that the toxin is inactivated by heating it at 80° C. for half an hour and that it cannot be formed in warm blooded animals. The results of the second series of inoculations convince us that our findings correspond to those of previous investigations. We also believe that the toxin ingested by the patients was not of a very virulent type because the symptoms cleared up in a short time. This may, however, have been facilitated by the early administration of the antitoxin. The fact that the guineapig first inoculated with the original culture did not show any marked symptoms until a second and much larger dose was administered, tends to strengthen our belief that the toxin was not very virulent, that in all probability the illness of the patients was brought on by eating the squash which was improperly canned at home. We were unable to demonstrate the toxin or the organism causing it in the squash because the original jar which was used at this dinner was not available for experimental purposes.

We are indebted to Miss E. F. Paul, our laboratory technician, for her careful work in aiding to clear up the diagnosis in these cases.

Primary Malignant Tumors of the Liver

By HYMAN I. GOLDSTEIN, M.D.,
Camden, New Jersey,
Assistant Visiting Physician, Philadelphia General Hospital; Assistant Chief Visiting Physician and Chief of the Medical Clinic, Northwestern General Hospital, Philadelphia

Cohn, of Spokane, Washington (1920), reviews some of the reported cases of primary sarcoma and carcinoma of the liver in his paper on Primary Cancer of the Liver. He states that "primary malignancy of the liver is a very rare condition. The number of instances of this disease is very small." My study of the entire literature of the world on the subject, and after a thorough search, leads me to believe that the authentic cases of primary cancer of the liver is much greater in number than those of sarcoma. I have collected fifty-nine instances of undoubted primary sarcoma of the liver. There are probably not more than two hundred or two hundred and fifty true instances of primary hepatic cancer on record in the literature. Cohn mentions cases of hepatic malignant diseases reported by Dickenson, Hale White, W. W. Ford, Wheeler, Muir, M. De Massary, Rohdenburg, J. B. Cleland, Delepine, Pepper, Heaton, Pitt, Wallstein, Freeman, Castle, Acland, Tate, Affleck, Roberts, Bramwell, La Page, Lewis, Yeomans, Williams, Perry, and Schlimpert. He includes a list of sixty-nine references on the subject. In view of the fact that primary malignancy of the liver is a rare condition I thought it worth while to add a report of twelve cases, and to review briefly the literature on the subject. While cancer of the liver in general is common, primary cancer is certainly most unusual. Thus, Hale White found at Guy's Hospital 244 cases of cancer of the liver from 1888 to 1906, forty-five cases of liver abscess, and forty-three of hydatid diseases. In 9,500 consecutive postmortems there were 361 examples of secondary malignant disease of the liver, and of these at least 330 were cancer. So 3.47 per cent. of all the people who die in Guy's Hospital have carcinomatous growths in the liver. H. D. Rolleston found that of seventy-six cases of secondary malignant diseases of the liver, the primary seat was in the stomach in twenty-four, in the colon in twelve, in the esophagus in ten, and in the pancreas in eight. It was primary (in Rolleston's series) in the gallbladder in five.

Ribadeau-Dumas and de Laulerie (1920) (12) reported a case of slow adenocarcinoma of the liver, which had run for five years.

Van Sweringen (1910) reported a case of sarcoma of the liver and stomach in a woman aged sixty years. No other metastases were found in the body. The liver was extremely large. However, it was considered by Lamb that the sarcoma in this case may have been primary in the stomach.

Up to November, 1901, there have been about fifty cases of probable primary sarcoma of the liver recorded in the literature. Of these thirty are without doubt true primary tumors of the liver.

Primary carcinoma with cirrhosis of the liver is not so rare as formerly thought. Sarcoma with cirrhosis of the liver is much rarer. Recently Dr. Alfred Stengel (1921) had a case of primary carcinoma of the liver with cirrhosis in an adult male. Finley and Adami reported a case with this combination. Fussell and Kelly (1895) reported two cases of a similar nature. Sotti, Thomson, Rispal, Thorel, Tollemer, Travis, and others have also reported cases of primary carcinoma of the liver with cirrhosis. Dr. Napoleon Boston had a case with this combination in the Philadelphia General Hospital.

W. W. Ford reported a case of primary sarcoma of the liver with cirrhosis which occurred in the Montreal General Hospital. The patient was a man aged fifty-nine years. There was a combination of an extreme grade of cirrhosis of the liver with a large sarcomatous mass in the right lobe, and a number of secondary nodules scattered throughout the peritoneal cavity.

PRIMARY CARCINOMA OF HEPATIC DUCT AND REGION OF FISSURE OF LIVER.

CASE I.—John Y., white, adult male, aged thirty-eight years. In January, 1920, he became jaundiced. Complained of pain and discomfort in the epigastric region. Severe itching kept him awake. The liver and gallbladder region was distinctly tender. The liver was enlarged. At first it appeared to be a case of catarrhal cholangitis following an attack of indigestion. The patient had, a week before he was seen, what he called a "spell of indigestion," which was followed by slight "yellowness of the skin." However, he rapidly became worse, the itching was very distressing, and he became more deeply jaundiced.

He was seen by Dr. D. Riesman, of Philadelphia, who at first thought he had a pancreatic tumor. I advised the man to be operated on, as did also Dr. Riesman.

The laboratory findings showed bile present in the urine, .7 per cent. urea; hyaline and granular casts present; specific gravity, 1.015. The blood showed 3,520,000 red blood cells; 60 per cent. hemoglobin; 80 per cent. polymorphonuclears; 15 per cent. lymphocytes; 5 per cent. large mononuclears. On January 30, 1920, the x ray taken by Dr. Roberts, was negative for tumor or stones. The liver extended a hand's breadth below the costal margin. The blood urea showed 10 mgms. per 100 c. c. blood. The phthalein renal function test was unsatisfactory, because of the bile in the urine. I suspected a probable malignant growth of the gallbladder and liver. The blood Wassermann was negative. On March 25, 1920, Dr. John B. Deaver performed a laparotomy at the Lankenau Hospital and found a primary carcinoma of the hepatic duct extending into the fissures of the liver. The patient died April 8, 1920, the day after he came home from the hospital, or about three months after the beginning of his illness. The remarkable fact was that his appetite was extraordinarily good during the entire period of his illness, and his gastric symptons were

comparatively slight. He did not suffer, except from the severe and distressing itching, due to the marked jaundice. He had no fever at any time. His pulse was 64-72.

CASES OF CARCINOMA OF THE LIVER AND BILE DUCTS.

Case II.—Autopsy No. 1904-129. June 14, 1904, Philadelphia General Hospital, University of Pennsylvania Autopsy Records, 1904, Vol. X, p. 43. Mary Jane F., aged seventy-four years. Admitted May 11, 1904; died June 13, 1904. Service of Dr. David Riesman. Autopsy performed by Dr. Alburger. The clinical diagnosis was phthisis pulmonalis, carcinoma of the liver. The anatomical diagnosis, carcinoma of head of pancreas and liver; chronic parenchymatous nephritis (left); tuberculous pyonephrosis (right); hemorrhagic enteritis; arteriosclerosis. The histological summary: Carcinoma, probably originating from the bile ducts and cirrhosis of the liver; fibrosis of the spleen; fibrosis (perilobular) of pancreas; chronic interstitial nephritis; slight fibrosis of adrenal. The stomach was small, mucous membrane thick and covered with mucus. The duodenum: below the papilla was a large ulcer four cm. broad, by 1.5 cm. long, with elevated thickened and hyperemic edges; depressed, yellowish, bile-stained centre. The small intestines, were normal throughout. The appendix showed no gross change. The common bile duct was involved in the carcinomatous process. The liver weighed 2450 gms. It was firm; covered by yellow nodules, supplanting the greater portion of hepatic structure, especially of the right lobe. The report by Dr. Loeb showed carcinoma of the glandular type in the liver, many mitoses, some increase of connective tissue in liver, probably carcinoma originating from bile ducts. The pancreas showed increase of connective tissue, especially perilobular; increase in size and number of the islands of Langerhans; round cell infiltration in the connective tissue; around the large ducts polynuclear leucocytes.

Case III.—Autopsy No. 1904-209. August 10, 1904. University Hospital, University of Pennsylvania Autopsy Records, 1904, Vol. X, p. 398. Maggie R., aged fifty-four years. Admitted July 13, 1904; died August 19, 1904. Service of the late Dr. J. William White. Autopsy performed by Dr. Coca. The clinical diagnosis was phlebitis; carcinoma of pylorus and liver. The anatomical diagnosis, cholelithiasis; carcinoma of liver (primary seat not discovered), extension to peritoneum, and mesenteric lymph glands; general arteriosclerosis; vegetative endocarditis (tricuspid and aortic) Histological summary: Infiltrating adenocarcinoma of bile ducts (carcinomatous cirrhosis) and slight fatty infiltration of liver; fibrosis of pancreas. Cancerous infiltration of abdominal lymph glands and of adrenal. Chronic interstitial splenitis; fibrosis and congestion of lungs.

The patient complained of pain in the right hypochondrium, a constant dull ache. The urine was negative. July 15, 1904, white blood cells, 15,240. July 25, 1904, white blood cells, 20,520, hemoglobin 75 per cent. The liver weighed 2220 gms. and measured twenty-six by twenty by twenty cm. On section the liver presented a mottled appearance. There were many nodules, firmer than the surrounding tissue and of a lighter color, showing almost no evidence of necrosis.

The cancer was of a tubular adenocarcinomatous type, apparently, from its similarity to the bile ducts having its origin in these. The relatively large amount and dense character of the fibrous stroma of the growth marked it as essentially a hard cancer. It would be classed with either the form of biliary cancer spoken of as Perl's infiltrating carcinomatous cirrhosis; or as the form arising from the larger gallducts and infiltrating the capsules of Glisson. In the sections examined the capsule was normal. The pancreas exhibited marked areas of interlobar cirrhosis, with here and there interacinous fibrosis of the same type.

The spleen had fibrosed trabeculæ and vessels, capsule was normal. In many instances the thickened vessel walls had become hyaline. The cancer in one of the adrenals was identical in type to that in the liver.

PRIMARY CIRRHOTIC BILIARY CARCINOMA.

Case IV.—Autopsy No. 1885-1908-7. January 12, 1908. University Hospital, University of Pennsylvania Autopsy Records, Vol. XVI, 1908, p. 26. Service Dr. J. B. Carnett. Autopsy performed by Dr. H. T. Karsner. Martha W., white. The anatomical diagnosis was biliary carcinoma; metastases to subhepatic glands and right adrenal; general jaundice; acute splenic tumor; chronic diffuse nephritis. The histological diagnosis, primary cirrhotic biliary carcinoma of the tubular type; chronic congestion of the spleen; chronic interstitial nephritis with implantation of acute parenchymatous. The patient was complaining of increasing loss of flesh followed by a gradually oncoming general jaundice for a period of several months. She had a hemorrhage and after operation, the bleeding continued up to the time of her death four days later.

The liver (pathological museum No. 217) weighed 2320 gms., measuring twenty-eight, by twenty-three, by 7.5 cm. It showed prolongation of a sharp anterior edge, the edge itself was of normal sharpness. In the right lobe was a large tumor mass, the mass was not sharply outlined but faded away into the hepatic tissue with almost no signs of pressure, apparently replacing the parenchyma. The tumor was grayish yellow in color with some pinhead points centrally placed of a deep yellow color with a peripheral zone of hemorrhagic points varying from bright red to a deep blue color. The consistency of this mass was somewhat firmer than that of the liver tissue and approximated that of hard rubber. The gallbladder was of about normal size. The cystic duct, common duct, and the hepatic duct were patulous. The ampulla showed a small soft gallstone, but showed no obstruction to the flow of bile through the duct at the postmortem examination. The glands of the transverse fissure were enlarged, hard and on section were found completely filled by a mass of tissue yellow gray in color, of a consistency similar to that of the liver tumor. The right adrenal was much enlarged and thickened, and showed posteriorly a mass corresponding to the mass of the enlarged glands.

The spleen showed slight thickening of trabeculæ and capsule, pulp shows normal elements.

PRIMARY BILE DUCT CARCINOMA OF THE LIVER.

CASE V.—Autopsy No. 1909-24 (2450). March 18, 1909. Philadelphia General Hospital. University of Pennsylvania Autopsy Records, Vol. XVIII, 1909, p. 99. Service of Dr. Henry. Autopsy by Dr. H. T. Karsner. Charles C., aged forty-nine years; male, white. Admitted to hospital January 28, 1909. Died March 17, 1909.

The clinical diagnosis was hypertrophic cirrhosis of liver; ascites.

The gross anatomical diagnosis: Metastatic carcinoma of lungs and pleura; cloudy swelling of myocardium; primary carcinoma of liver, infarcts of spleen; secondary cancer in left kidney and retroperitoneal lymph nodes and of pancreas. The histological diagnosis: Passive congestion and tumor metastases of lung, edema. Slight chronic interstitial myocarditis, infarct of papillary muscle; primary bileduct carcinoma of liver; chronic fibrous splenitis and perisplenitis, anemic infarct of spleen. Subacute parenchymatous nephritis and tumor metastases.

The liver weighed 3300 gms., measured twenty-eight by twenty-three by eleven cm. It was firm and abnormally rounded. The liver substance was seen through the transparent capsule to be studded with innumerable grayish yellow nodules with umbilicated surface, generally rounded, discrete and confluent, varying in size from a diameter of one mm. up to four cm. The organ cut with moderately increased resistance. The uninvolved liver tissue was small in amount. The gallbladder was normal. The pancreas showed a metastatic nodule in its head, which was partially encapsulated by fibrous tissue. Microscopically, the liver capsule was thickened by an overgrowth of dense fibrous tissue. The capsule of Glisson shows a wellmarked fibrous tissue overgrowth and some lymphocytic infiltration. The veins were moderately congested and the arteries showed slight thickening of their walls. The epithelial cells were columnar in type and arranged in the form of irregular tubular or acinous masses, either solitary or continuing toform large infiltrating areas. The cells corresponded closely to those of the bile ducts, being low columnar, only moderately acidophilic, and with relatively small circular vesicular nuclei. Considerable variation was noted in the character of the epithelial cells of the proliferating masses. The tumor as a whole showed few karyokinetic figures. Fibrosis about the central vein could be seen but no congestion was noted.

CASE VI.—Autopsy No. 56-1909. April 14, 1909. Philadelphia General Hospital, University of Pennsylvania. Autopsy Records, Vol. XVIII, 1909, p. 238. Service of Dr. Sykes. Autopsy by Dr. H. T. Karsner. Frederick H., aged fifty-three years, white. Admitted to hospital April 12, 1909; died April 14, 1909. The gross anatomical diagnosis was tumor metastases in lungs; chronic adhesive pleurisy; primary cancer of bileducts and liver (with atrophic cirrhosis). Acute splenic tumor; arteriosclerotic kidneys, chronic interstitial nephritis, tumor metastases in prostate and mediastinal retroperitoneal and mesenteric lymph glands. The histological diagnosis: Tumor metastases in lungs, passive congestion and edema. Tumor metastases to diaphragm, prostate, and lymph glands. Chronic interstitial splenitis, chronic interstitial pancreatitis, chronic interstitial nephritis; primary cancer of sclerotic type of bileducts and liver. Atrophic cirrhosis of liver.

The liver weighed 2700 gms., measured thirty-one by eighteen by nine cm. The surface was markedly irregular and nodular, adherent to omentum. Many nodules of yellowish appearance showed through the capsule, others showed a dark red color, none showed umbilication. The organ cut with increased resistance and in the right lobe marked atrophic cirrhosis was present. The left lobe was enormously enlarged and showed little remaining liver tissue. Cross section showed necrotic nodules varying from a diameter of one mm. to five cm. The edges were not sharply outlined and tended to fuse with irregular bands of connective tissue about them. The gallbladder showed a normal mucosa and patulous ducts. The pancreas, was seventeen cm. in length and embedded in a mass of enlarged lymph nodes from which it could be separated with difficulty. Subhepatic and retroperitoneal lymph nodes showed enormous enlargement. The spleen weighed 200 gms., measuring 15.5 by ten by three cm. The stomach, duodenum, intestine contained nothing of importance. The mediastinal lymph nodes were enlarged and contained metastatic nodules. The liver microscopically showed an enormous fibrosis. The capsule and capsule of Glisson both apparently taking part in this, and marked proliferation of the bileducts was found. Large cell masses such as seen in the lungs were numerous and intermediate in size between these large masses and the smaller bileducts could be found all grades. In the lungs were seen large masses of epithelial cells; these were markedly irregular in size and shape, and showed irregularity in position.

PRIMARY CARCINOMA OF THE LIVER WITH CIRRHOSIS.

CASE VII.—6852-1920-412. November 11, 1920. Autopsy Records, University of Pennsylvania. Prof. Alfred Stengel's Service at University Hospital. Autopsy by Dr. J. Eiman. Charles V. V., Admitted to hospital November 8, 1920. An elderly white man, measuring 195 cm., and weighing 200 pounds. Blood urea—nitrogen 46 mgm. per 100 c. c. Phenolsulphonephthalein elimination was 65 per cent. in two hours. He vomited large amounts of bright red blood. The patient died November 10, 1920. The clinical diagnosis was cirrhosis of the liver. The gross anatomical diagnosis: Carcinoma of the liver —primary, with metastasis to glands in gastrohepatic omentum, myocardium, right kidney, bronchial glands. Laennec's cirrhosis of the liver; varicosities of esophageal plexus of veins causing massive hemorrhages; parenchymatous myocarditis, fatty degeneration and dilatation; metastastic cancer right pleura; passive congestion and edema of lower lobes of lungs; spleen, chronic interstitial splenitis, and passive congestion; atrophy with fat replacement of pancreas; cloudy swelling of kidneys; moderate arteriosclerosis. The common duct was patulous. The liver weighed 2170 gms., measuring twenty-eight by twenty-two by nine cm., typical hob nail edges and round. In the central part of liver was a tumor mass, the size of a lemon, irregular, not circumscribed, and showed no evidence of encapsulation. It cut with increased resistance and was yellowish white in color, with small irregular reddish

areas. There were apparently no other tumor masses in the liver. The glands around the neck of the gallbladder and in gastrohepatic omentum were enlarged, the largest one being two cm. in diameter; they were similar in appearance to the tumor in the liver. The gallbladder showed a uniformly thickened wall. The mucosa was bile stained, but smooth. It contained watery, pale amber colored bile. The pancreas showed no evidences of neoplastic growth, neither did the stomach and adrenals. The spleen weighed 840 gms., measured twenty-five by fifteen by four cm. The surface showed *Zuckerguss* patches. The capsule was slightly wrinkled. The organ was leatherlike in consistency. The pulp was very firm. The left kidney weighed 250 gms., measured 15.6 by 7.5 by four cm. The right kidney weighed 260 gms., measured fifteen by eight by three cm. Showed a small metastatic nodule in the cortex. In the diaphragm were embedded small metastatic nodules, the largest one about four mm. in diameter. The lower fourth of the lower lobe of the right lung showed numerous firm whitish nodules, varying in size from a pinhead to a split pea. They were attached firmly to the pleura and did not penetrate into the lung tissue. The endothelial surface of the diaphragm showed similar nodules. The heart showed a moderate right sided dilatation; sixteen by sixteen by 4.3 cm., and weighed 400 gms. It is very flabby. In the wall of the left ventricle there was embedded a firm whitish spherical node about five mm. in diameter. The endocardium showed no gross lesions. The bronchial glands were markedly enlarged, and the lymphoid tissue was almost entirely replaced by neoplastic growth. The largest lymph node measured 1.5 cm. in diameter. They were firm, and cut with increased resistance. The mesentery was thick, but showed no glandular enlargements.

PRIMARY BILIARY CANCER.

Case VIII.—No. 213, page 22. Vol. II. Records of Pathological Histology, University of Pennsylvania. (Dr. H. W. Cattell.) Examined by Professor Allen J. Smith, May 31, 1904. Mrs. H. A diagnosis of soft cancer (cylindrical cell epithelioma) of liver and lymph gland was made. The growth had its origin in the gallducts, probably at the site of the large degenerate node.

Professor Smith in his description states the type of cells is probably primarily a cylindrical epithelium; but only in picked places is this clear. For the most part the cells are larger and rounder or more irregular than ordinarily seen in a true cylindrical cell epithelioma. They are full of cell inclusions, and often are highly suggestive of sporozoan figures, but the examiner was unwilling to declare for such a nature of growth although recognizing its suggestive features. In some respects too the appearances are strongly suggestive of the hypernephromata, although the cells are scarcely large enough and contain too few of the droplets or tiny vacuoles so common in such tumor cells. There is insufficient definite relation with the vessels to permit the diagnosis of an endothelioma or perithelioma of vascular origin. The most reasonable diagnosis in the examiner's mind is that of a soft cancer of the nature of a cylindrical cell epithelioma, arising from some tubular type of gland structure. In the absence of other known seat of primary tumor, taking into consideration the size of the hepatic node and the appearance of some of the tumor tubules seen especially in the infiltration of the capsule of the hepatic node, it may be suggested that the growth had its origin in the gallducts probably at the site of this node.

PRIMARY SARCOMA OF THE LIVER.

Case IX.—4178—1913—63. April 29, 1913. Autopsy Records, University of Pennsylvania. Autopsy by Dr. Lynch. Service of Dr. Ashton, Philadelphia General Hospital.

Charles K. White, male, aged thirty-eight years. The gross anatomical diagnosis was chronic aortic and mitral valvulitis, acute vegetative aortic endocarditis; chronic apical tuberculosis, passive congestion and edema both lungs; acute splenic tumor, parenchymatous and fatty degeneration of the liver; parenchymatous degeneration of pancreas; arteriosclerosis; chronic fibrosis serositis, peritoneum, pleura and pericardium; loculated purulent peritonitis with communication with psoas muscle and liver abscess. The histological diagnosis was chronic fibrous epicarditis, myocarditis and endocarditis, parenchymatous degeneration; croupous pneumonia, chronic fibrous pleuritis; chronic fibrous splenitis (interstitial), chronic fibrous capsulitis, with passive congestion. Chronic fibrous capsulitis with early portal cirrhosis of the liver, organizing abscess, spindle cell sarcoma arising from the wall of a chronic abscess; parenchymatous and fatty degeneration of the liver; chronic interstitial nephritis, arteriosclerotic type, parenchymatous degeneration and passive congestion of the kidneys (bilateral nephrolithiasis). The spleen weighed 250 gms, measured sixteen by eight by 3.5 cm., thick, fibrous ragged capsule; soft, dark red and diuent pulp. The bacteriological examination of the abscess: spreads—Bacillus diphtheria, Bacillus coli, pneumococcus; tubercle bacillus not found. Liver: diplococcus, Bacillus coli. The spleen: negative. Cultures: abscess: Bacillus diphtheriæ, diplococcus, Bacillus coli. Liver: staphylococcus, diplococcus, Bacillus coli and diplococcus.

The body was that of an adult white male with kyphosis in the lumbar and lower thoracic vertebra, barrel chest, small stature, protruding abdomen, slightly emaciated. The pancreas was normal in size, pale, soft, and lobules indistinct. The adrenals were nodular, yellowish cortex, very soft, reddish medulla. The heart weighed 300 gms., no metastatic nodules; surface is rough and fibrous, showing numerous petechial hemorrhages; myocardium of normal thickness, pale and flabby. The liver weighed 1,650 gms, measuring thirty-five by nineteen by eight cm. with an abscess cavity on the under surface of the left lobe. The capsule was enormously thickened. One portion of the section from abscess wall was composed of masses of young, spindleshaped cells, running in an irregular fashion, practically no intercellular substance, with active hyperchromatic and mitotic nuclei, large numbers of endothelial lined blood channels, there was no capsule. Penetrating directly in the inner portion of the section was a mass of young and old fibrous connective tissue, well formed congested bloodvessels and one portion of the section showed extensive degeneration and necrosis. The spindle cell sarcoma was primary in the liver in this case. No metastases were present anywhere else in the body.

PRIMARY CARCINOMA OF THE LIVER.

CASE X.—Autopsy No. 144; 1902. June 4, 1902. University of Pennsylvania Autopsy Records, Vol. VII, p. 345. Autopsy performed by Dr. W. T. Longcope. Blockley Hospital. J. A. Death occurred on June 3, 1902. The clinical diagnosis was hepatic carcinoma. The anatomical diagnosis: Primary carcinoma of liver, with metastases to retroperitoneal lymph glands; occlusion of cystic duct; dilatation of gallbladder; interstitial splenitis and nephritis; chronic pulmonary tuberculosis, acute bronchopneumonia, general icterus. The body was that of an old emaciated man.

The liver weighed 4,780 gms.; enormously enlarged, measured thirty by thirty-two by twelve cm. The surface was covered with old tags of fibrous tissue; when these were removed the entire liver was found to be studded with yellowish gray nodules measuring from two mm. to 1.5 cm. in diameter; these were placed very closely together and the largest ones which showed a pinkish periphery, present a contracted scarlike appearance. The general surface of the liver between these nodules was of a mottled olive green. All the lobes on both anterior and posterior surface presented this same knobbed appearance. The gallbladder was much enlarged, elongated and measured 15.5 cm.; near its tip the wall were thickened and there is a slight constriction. The cystic duct as it left the gallbladder was blocked by a large stone the size of a marble; directly adjacent to this there was an enlarged lymph gland about the same size. On section of the liver, the surface was irregularly lobulated and studded like the capsule with firm yellow and red nodes projecting from a brilliant green surface; these projections were frequently round and quite regular, the centres being a brilliant opaque yellow and the peripheries a fairly deep red. There was no softening to be found anywhere. Esophagus, stomach, intestines, adrenals, prostate, testicles, seminal vesicles, rectum, pericardium were apparently normal.

The lower border of the pancreas was adherent to a firm mass about the size of a walnut; this mass was bound to the pancreas and to the retroperitoneal tissues by firm adhesions but appears distinct from the pancreas. On section it has a mottled yellow and gray appearance, firm yellow areas frequently being surrounded by irregular hemorrhagic zone. The retroperitoneal glands were somewhat enlarged; those about the common bile duct showed the greatest increase in size; they were firm and on section appear similar to the gland attached to the pancreas. None of them were more than two cm. in diameter. The spleen weighed 110 gms., deep purplish red color; small, firm; on section pulp is deep red and increased.

PRIMARY CARCINOMA OF THE BILE DUCTS.

CASE XI.—Carcinoma of the liver, and secondary carcinoma of the pancreas. Autopsy No. 119—1908—2135. Vol. XVII, p. 70. University of Pennsylvania, Autopsy Records. Autopsy performed by Professor Allen J. Smith, June 14, 1908. Service of Dr. L. Napoleon Boston, Philadelphia General Hospital, Philadelphia. E. S. Admitted to the hospital May 11, 1908, died June 13, 1908.

The clinical diagnosis was carcinoma of bile ducts (primary) carcinoma of liver; secondary carcinoma of pancreas (?). The gross anatomical diagnosis: Primary carcinoma of gallbladder with extension to liver and metastatic involvement of gastrohepatic glands; cholelithiasis, obstructive jaundice; follicular hyperplasia of the spleen; nephrolithiasis; aortic sclerosis and atheroma. The histological diagnosis: Chronic interstitial pneumonitis, miliary tubercles (?) of lung, chronic tuberculous peritracheal lymph adenitis, cardiac hypertrophy and chronic interstitial myocarditis; primary cancer of gallbladder with extension to liver; chronic interstitial nephritis; extension of cancer to right adrenal gland.

On appearance the body of a white woman, past middle life, five feet in height, weighing approximately 125 to 130 pounds, with marked jaundice. The spleen weighed 240 gms., nonadherent, roughly quadrate in outline, measured eighteen by eight by five cm. The organ was of a gray slaty color, normal consistence. The liver weighed 2,400 gms., measured twenty-eight by twenty-four by eight cm. It presented numerous bulging yellow nodules on the upper and lower surface; organ was olive in color; capsule smooth and transparent (small area of sclerotic thickening in vicinity of tumor nodule), and seen through the capsule the lobules could be made out as yellowish points with intervening lines of darker color.

CONCLUSIONS AND SUMMARY.

1. In a study of the literature of the world, the autopsy records of the University of Pennsylvania, reports from hospitals, clinicians, and surgeons in all the large medical centres of the United States, I have been able to collect the following cases: primary sarcoma of the liver, fifty-nine; primary sarcoma of the pancreas, twenty; primary sarcoma of the gallbladder, sixteen; primary sarcoma of the esophagus, thirty-eight; primary sarcoma of the tongue, sixty-six; primary sarcoma of the stomach, 266, 139 of the small and large intestines; eighteen of the appendix (including my own case); sixty-six of the spleen and 125 cases of primary sarcoma of the thyroid gland. Six cases of intestinal sarcoma I hesitated to include in my list of 139, and six cases of esophageal sarcoma were not included in my list of thirty-eight, because of some doubt as to the primary origin of the growth. In other words, after a careful search of the literature, I was able to collect about 813 cases of primary sarcoma in the entire alimentary canal (including the tongue, esophagus, stomach and intestines), the liver, gallbladder, pancreas, appendix, spleen, and the thyroid gland.

2. There are about two hundred and fifty cases of primary cancer of the liver on record in the literature. I was only able to find fifty-nine cases of primary sarcoma of the liver in the literature.

3. A review of the literature of primary malignant tumors of the liver is given.

4. Cases of primary cancer and sarcoma of the liver are reported.

I wish to express my thanks for the assistance given me by Professor Allen J. Smith, of the University of Pennsylvania, and for his permission to study and review the excellent autopsy records kept by him (1876-1920), and for the privilege to make the notes on the cases herein reported.

1425 BROADWAY.

Practical Therapeutics

DIETETIC TREATMENT OF OBESITY*

EDWARD E. CORNWALL, M.D., F.A.C.P.

Brooklyn, New York

Obesity, as generally understood, means a condition of overweight due to an excessive accumulation of fat in the body, and does not include such definite endocrine diseases as myxedema, dystrophia adiposogenitalis and adiposa dolorosa.

The average healthy body contains stored fat amounting to about eighteen per cent. of its weight, but each individual has his own particular, preferred weight, which may differ within moderate limits from the average weight for his height and age without suggesting a pathological condition. This preferred weight he regularly maintains so long as he eats enough, and even when he eats more than enough. Indeed, it is a matter of common observation that healthy persons can maintain a constant weight when eating more food than they require for size, age, temperature and work, and in some cases much more. It would seem as if they got rid of the excess food by speeding up combustion, by exercising reserve functional power.

It is also a matter of common observation that the obese can not eat much more food than they need without storing fat; and it is a natural inference, in view of the fact that basal metabolism in the obese has not been demonstrated to be regularly below that in the healthy, that in the former the particular reserve functional power which has to do with excess combustion, with speeding up combustion in the presence of more food than the body needs, has been encroached on or is congenitally small. The margin between the maintenance diet and that at which deposition of fat begins, which is large in the healthy, is relatively small in the obese. M. Labbé (1) says that the obese increase in weight more easily and reduce in weight with greater difficulty than others. Their luxus consumption, to use Richet's phrase, is less than the average of health.

All cases of obesity are not necessarily due to gluttony, nor are all gluttons necessarily found among the obese. These clinical observations receive support from the studies of Jacquet and Svenson and others, who found in obese subjects normal consumption of oxygen while fasting, but a smaller increase in combustion after eating than in healthy subjects. Also, it has been noted that the obese have greater difficulty in radiating heat than the healthy; which can be explained by the fact that the former are encased in a thicker envelope of fat than the latter.

The treatment of obesity has for its object the burning up of excess fat in the body and the preventing of its reaccumulation. The safest as well as the most effective method of accomplishing this object consists in dietetic regulation and hygiene.

The regulation of the diet has first to do with its fuel value. Assuming that basal metabolism in the obese is normal, and that a person with normal basal metabolism can maintain his body weight by a daily ration of twenty-five to thirty calories to the kilogram of his ideal weight (average weight for height and age) while at rest, of thirty to thirty-five calories while leading a life of little or moderate activity, of thirty-five to forty calories while leading a life of considerable but not great activity, and of forty to forty-five calories while leading a very active life, it follows that the calculation of the caloric value of a reduction diet can be made by subtracting from the caloric value of the maintenance diet the number of calories that could be supplied by the combustion of the body fat which it is desired to remove. The combustion of one ounce of body fat would supply about 250 calories. (One ounce of pure fat would supply 270 calories, but the body fat is associated structurally with some water.)

In this connection it may be noted that in cases of obesity individuals may differ in the residuum of reserve combustion power which they possess, that residuum being in some cases large enough to permit a considerable allowance to be made for it in calculating the fuel value of the reduction diet. There may be different grades of obesity, as there are of diabetes.

While reduction of the fuel value of the diet is essential in the treatment of obesity, indications for regulating the diet in other respects are frequently present. Obesity is often found, not as a simple and isolated entity, but complicated by or associated with other morbid conditions. It has close relationships with disorders of protein and carbohydrate metabolism. Gout and gravel occur relatively often in the obese, and diabetes mellitus develops so frequently in the obese that the prevention of obesity is considered an important prophylactic measure against diabetes. The obese are favorable subjects for chronic nephritis, chronic arthritis and arteriosclerosis. Myocardial disease is a common complication of obesity. In the cases developing in middle and later life, which constitute the majority of the cases, regulation of the diet otherwise than by reduction of its fuel value is usually required.

Most important in the regulation of the diet after reduction of its caloric value, is the determination of the size and character of its protein ration. The specific dynamic action of ingested protein on metabolism in the body is greater than that of either carbohydrate or fat, and consequently a large ration of protein would seem to be indicated for the purpose of speeding up combustion. But the presence of the gouty diathesis of nephritis, or of an undue susceptibility to the toxins which are produced from protein food during its digestion and metabolism, may modify the indication for a large protein ration, and also suggest that the selection of food articles containing protein favor those whose protein is most free from association with undesirable substances and least susceptible to injurious bacterial activity; that is, that this selection be in accord with the principle of the easy diet (2).

In view of these considerations it would seem, in general, that the protein ration in obesity should be

*Read before the American Therapeutic Society, Toronto, June 7, 1924.

somewhat larger than the minimum health ration, in so far as other conditions permit; that in the elderly and in those cases complicated with gout, nephritis, arteriosclerosis and perhaps rheumatism, it should be derived from milk or milk and eggs, in preference to animal flesh, although in many of these cases a certain amount of flesh is permissible; and that in uncomplicated cases occurring in the comparatively young, no special restriction of flesh is called for.

The relative proportions of the fat and carbohydrate in the diet are usually determined by the principle that the fuel deficit should fall chiefly on the fat. The specific dynamic effect of ingested carbohydrate is greater than that of fat, though less than that of protein.

The water ration, except in the case of patients with advanced myocardial disease which requires restriction of fluid, should be large enough for comfort but not excessive. Restriction of fluid does not seem advisable as a general antiobesity measure, although such restriction may to a certain extent and for a time reduce the weight. Obese patients undergoing reduction treatment sometimes seem to retain water in their tissues unduly; also, especially in the beginning of a course of treatment, it would seem sometimes as if the elimination of water was increased.

A patient should not be kept on a reduction diet for long periods without intervals of rest, in which a sufficient or slightly excessive diet is given: the excess combustion power may show improvement after being rested.

It is not advisable to reduce the weight rapidly, and a good general rule is to limit the average weekly reduction to two pounds, which can be accomplished, theoretically, by giving a diet which has a fuel value less by about one thousand calories than the normal fuel requirement, and usually practically by such a diet. In many cases the reduction should be made at a slower rate than two pounds weekly.

It is often necessary to restrain patients who desire to reduce too rapidly, and to make sure not only that they eat no more than what is prescribed for them, but that they eat no less.

The young and the very old should not, as a rule, be subjected to reduction treatment, before the age of twenty practically never, except by the correction of wrong diet, and after fifty with caution, being guided by the condition of the patient. Those entering on old age who have been obese for a long time should not be reduced, and great caution should be exercised in reducing those who have serious diseases, if it is done at all. In any case showing symptoms of distress the rigidity of the diet should be relaxed or a return made to the normal diet. The reduction should not be carried to an extreme degree. A general rule which the author favors is not to produce a reduction of more than twenty-five pounds in the first course of treatment. In obesity complicated with heart disease it is desirable to reduce the weight before there is loss of compensation. When there is edema with obesity and heart disease, reduction should not be undertaken.

The treatment may be begun by giving an arbitrary diet and varying that according to indications, or an attempt may be made to construct an appropriate diet based on the normal caloric requirement of the individual for his particular grade of life activity. A person whose ideal weight is sixty-five kilograms, would require daily about 2,300 calories for a life of moderate activity; and for such a person a diet designed to produce a loss of two pounds of weight weekly, would be one which supplied about 1,300 calories. Often it is advisable to begin and continue with a less reduced diet. Rarely is it advisable to give a diet supplying less than 1,200 calories.

Ordinarily the patient can continue his customary activities while taking the reduction diet, but advantage is sometimes obtained by beginning the course of treatment with rest in bed for a short time, and giving a diet which supplies 500 calories less than the basic caloric requirement. (The basic caloric requirement can be calculated approximately by multiplying the ideal weight in kilograms by twenty-five.) When the patient is out of bed, he may be given the fuel necessary for the more active life, less by the number of calories which it is desired to secure from the combustion of his body fat.

The hygienic treatment of obesity has particularly to do with exercise. Exercise makes for better circulation and elimination and deeper breathing. But limitations are imposed on the obese in the matter of exercise, both by the obesity itself and by complications. In cases complicated by heart disease rest may be required in greater or less amount, and the exercise allowed may require to be very strictly regulated. If the obese patient's habit of life is one of moderate activity, it is usually well to have it continue so. Advantage may be gained by letting the patient know that the treatment of his obesity calls for no change in his ordinary ways of life, but only in his diet.

The following prescription presents an example of a diet for obesity of a general character which can serve as a basis for individual modification.

OBESITY DIET

Protein, 84 grams; fat, 56 grams; carbohydrate, 127 grams; calories, 1350.

BREAKFAST

Grapefruit, strawberries, tomato, 180 gm. (6 oz.); or orange, apple, peach, muskmelon, watermelon, blackberries, huckleberries, 120 gm. (3 oz.).
Oatmeal porridge, or similar cereal, 90 gm. (3 oz.).
Bread, 15 gm. (½ oz.).
Eggs, two.
Milk, 240 gm. (8 oz.).
Coffee, tea, cocoa shells, clear infusions.

DINNER

Cooked spinach, string beans, wax beans, celery, chard, okra, beet top or dandelion greens, cabbage, cauliflower, sea kale, brussels sprouts, oyster plant, tomato, 180 gm. (6 oz); or carrot, squash, turnip, beet, 90 gm. (3 oz.).
Raw lettuce, endive, celery, cabbage, tomato, cucumber, 120 gm. (4 oz.).
Boiled, broiled, or roasted fresh beef, mutton, lamb, chicken, 90 gm. (3 oz.).
Boiled or baked potato, boiled rice, boiled macaroni, 90 gm. (3 oz.).
Bread, 30 gm. (1 oz.).
Butter, 7 gm. (¼ oz.).
Lemon juice on salad as wanted.

SUPPER

Fruit as at breakfast and cooked vegetables as at dinner.
Milk soup, viz., cream of corn, celery, asparagus, tomato, carrot, spinach, oyster plant, onion, 210 gm. (7 oz.); or milk, 240 gm. (8 oz.).
Cottage cheese, 60 gm. (2 oz.).
Bread, 30 gm. (1 oz.).
Butter, 7 gm. (¼ oz.).

The diet given above can be made completely lacto-vegetarian by substituting milk, skimmed milk, buttermilk and cottage or other cheese for the animal flesh and eggs. Often one or two eggs can be allowed in the diet when flesh is considered undesirable; and in many of the elderly patients and complicated cases a small amount of flesh can be allowed occasionally with advantage. For changing the character and amount of the protein ration and increasing and diminishing the fuel value of the diet, the following short lists of approximate equivalents are offered suggestively:

Containing Approximately Twelve Grams of Protein With Varying Fuel Values

Meat, lean, cooked, 45 gm. (1½ oz.); calories, 110.
Fish, lean, cooked, 60 gm. (2 oz.); calories, 50.
Eggs, two; calories, 150.
Egg, one, and bacon, fried, 30 gm. (1 oz.); calories, 225.
Egg, one, and milk, 180 gm. (6 oz.); calories, 195.
Egg, one, skimmed milk, 180 gm. (6 oz.); calories, 135.
Egg, one, cottage cheese, 30 gm. (1 oz.); calories 105.
Milk, 360 gm. (12 oz.); calories, 240.
Skimmed milk, 360 gm. (12 oz.); calories, 120.
Cottage cheese, 60 gm. (2 oz.); calories, 60.
Cream cheese, 60 gm. (2 oz.); calories, 100.
American cheddar cheese, 45 gm.; calories, 200.

Possessing Fuel Values Approximating 100 Calories, and Containing Small Amounts of Protein

Bread, 40 gm. (1⅓ oz.); protein, 3 gm.
Cereal porridges, 120 gm. (4 oz.); protein, 4 gm.
Potato, boiled, 100 gm. (3⅓ oz.); protein, 3 gm.
Banana, 100 gm. (3⅓ oz.); protein, 1 gm.
Orange, 270 gm. (9 oz.); protein, 1 gm.
Apple, 300 gm. (10 oz.); protein 1 gm.
Cream, 50 gm. (1⅔ oz.); protein, 1 gm.
Butter, 15 gm. (½ oz.); protein, 0 gram.
Bacon, fried, 20 gm. (⅔ oz.); protein, 3 gm.

A prescription for a daily diet of a very strict character, which might be used in special cases, is the following, which supplies protein, 80 grams; fat, 10 grams; carbohydrate, 200 grams; and calories, 1,200 grams. Two quarts of skimmed milk, one quarter pound bread, one pound green vegetables of small carbohydrate content, and two oranges.

CONCLUSIONS

In concluding, I wish to emphasize the following points:

1. Obesity is a common disease whose prevention and cure or amelioration mean much for the life and happiness of many; and its treatment in suitable cases by dietetic regulation is safe and generally effective at the hands of trained physicians; but dangers may attend its treatment by unskilled persons.

2. The rate of the reduction in weight should be slow, as a rule not exceeding the average of two pounds weekly; and the fuel value of the daily diet should be not less, as a rule, than 1,200 calories, and usually more than that.

3. The contraindications to reduction should be kept in mind, and reduction should never be pushed in the presence of untoward symptoms.

4. It is not enough, in most cases, to diminish the fuel value of the diet; the diet should also be regulated in other ways so as to favor complicating and associated morbid conditions.

ARSENICAL PREPARATIONS IN THE TREATMENT OF SYPHILIS

Charles Greene Cumston, M.D.
Geneva, Switzerland

Too much attention cannot be given to the arsenical products at present so extensively used in the treatment of syphilis, and for this reason the recent utterances of Milian, of Paris, who has done so much to advance this treatment, are of interest. The first precaution in giving an intravenous injection is to give it slowly, and Rober's experiments in this direction are conclusive. This rule is imperative in the administration of the arsenobenzols for the reason that when they cause accidents, these occur quickly.

Let us suppose that a nitritoid paroxysm arises one or two minutes after the beginning of the injection. If the injection is being given slowly and the solution well diluted as it should be, since it requires about ten minutes to complete the injection, it can be stopped the instant the first symptom appears, thus controlling the intensity of the paroxysm. On the other hand, if a concentrated solution is used, the probability will be that most of the drug will have entered the circulation when the attack begins, so that all control over it is lost, and Milian very correctly says that injections made by Ravant's technic cannot be given with the necessary slowness.

Dilute solutions only should be used and precautions should be taken, similar to those employed against anaphylaxis, by first injecting one cubic centimetre of the solution, then waiting about fifteen seconds before injecting another cubic centimetre. This should be done a third time and the rest of the solution then slowly injected. This technic should be adopted in every case when the treatment is begun, and from what has been observed in the Geneva clinics, I would add that it should be the routine practice if accidents are to be avoided.

As you know, Milian introduced the use of adrenalin as a treatment of nitritoid crises and he very rightly objects to its indiscriminate use as a prophylactic. As no reaction takes place after its administration, the practitioner, deceived by this fact, is apt to give a too large dose of the arsenical product so that accidents occur later and then the adrenalin may not be effective in counteracting them.

Suppurative Otitis Media Treated by Zinc Ionization.—T. B. Jobson (*British Medical Journal*, March 1, 1924) believes that zinc ionization is the most efficient method of treatment of tympanic sepsis of a certain type. It is not suitable for acute or subacute cases or for attic cases with cholesteatoma. Of course, in treating any case of otorrhea, oral and postnasal sepsis must be eliminated to prevent infection. The criterion of suitability is an open tympanum with an adequate perforation leading to it in which the sepsis is limited to the tympanic cavity. A tympanum "closed" by polypi or cholesteatoma is unsuitable. The advantages of treatment by ionization are: 1. It will cure any case of otorrhea which is curable by drops. 2. It will accomplish this in one hundredth part of the time, thus saving an enormous amount of the patient's, doctor's, and hospital's time. 3. It will cure a large number of cases which do not mend with ordinary antiseptic treatment.

Historical Medicine

Mention Made of the Fingers by Rabelais

DOUGLASS W. MONTGOMERY, M.D.,
San Francisco

No direct medical reference to the fingers is made by Rabelais. They are only referred to as organs of expression, or on account of their connection with medical superstitions. Any mention of the fingers, however, by the most objective genius who has ever occupied himself with writing about human physical peculiarities cannot be without interest.

In modern clinical medicine, the hands, together with the hair, scalp, face and neck, as being exposed, afford a physician, most easily and swiftly, a general idea of the condition and constitution of the patient. Besides, there has grown up of late years a vast literature, touching the symptomatology, pathology and treatment of the fingers and hands, as for instance, their aspect in acromegalia, in myxedema, and in other interesting conditions.

The fingers and hands of the physicians and surgeons themselves have taken on an ever increasing importance since Rabelais's day, both as instruments of education for the acquisition of facts and ideas, and on account of their manipulative dexterity. Rabelais, however, recognized what faithful, useful servants they are in the scene in which the companions of Pantagruel tell their magnanimous chief that he might depend upon them as upon the fingers of his own hands (1).

WOUND OF THE FINGER

In Pantagruel, Rabelais enumerates a number of curious ways in which death may supervene, and among others, of a Roman on whose tomb on the Flamminian Way the epitaph stated that he died by being bitten on the little finger by a cat. Le Duchat, with his accustomed erudition, has dug up the reference, and it appears that the good man's heirs drew the attention of the passerby to this new kind of death (novum mortis genus), and at the same time, took the opportunity to express their disapproval of the cat (*improba felis*) (2). The same type of mind nowadays would give a short dissertation on infected wounds, equally for the edification of the same passerby.

THE ITCH IN ITS RELATION TO THE FINGERS

Rabelais repeatedly mentions the *ciron*, the itch mite, and especially that it is found between the fingers (3). He, the epitome of the folklore of the Middle Ages, knew of the itch mite long before the Corsican, Ranucci, demonstrated it in Albert's clinic in Paris. In fact, Ranucci's demonstration was made from what he learned from the Corsican peasant women. Equally interesting is the fact that the Genovese galley slaves used mutually to relieve one another of their itch mites by picking them out. These sharpeyed youngsters, driven by that great mother of invention, necessity, found the itch mite long before the learned physicians were aware of it. By the way, it may be remarked that the itch mite can just be seen with the naked eye as a little white speck on the point of a pin. The itch was extremely prevalent in the Middle Ages; poor hygiene and promiscuity would see to that, as it did in the recent Great War.

A further value to these references, besides the priority of observation, lies in the fact that a great scholar like Rabelais, acknowledgedly the greatest of his time, was yet broadminded enough to note an observation appertaining to the common people. This broadness of view and hospitality to observation is characteristic of Rabelais, who lived at a time when narrowness of view and hostility to observation was by far the more prevalent attitude.

INTERLACED FINGERS AS A PREVENTION OF CHILDBIRTH

One of the most interesting references to the fingers is where the jealous and angry Juno held her fingers interlaced to prevent Alcmena giving birth to Hercules. The following is an abstract of the tale as related by Pliny.

To remain seated with the fingers interlaced near a pregnant woman, or a person who has taken medicine, is maleficent witchcraft. It is still worse if the fingers are clasped over one or both knees. It is also maleficent, in the same sense, to cross the legs, no matter which leg is uppermost, or alternately so. Our forefathers, Pliny further stated, forbade generals and magistrates in their assemblies to assume this posture, as constituting an obstacle to everything under discussion.

This rule might act excellently in a rather unexpected way. In a deliberative assembly the members are usually past middle age, and therefore, at a time of life when the body, especially the lower part of it, together with the knees and the legs are breaking down. For example, it is an old saying that the knees give way before the head. These people, therefore, are subject to all sorts of uneasiness from hernias, piles, fissures of the anus, intertrigo, irritable bladder, pains in the legs, varicose veins and rheumatism of the knees and ankles, and any rule denying them change of posture might readily act as a sort of cloture or abbreviator of the session.

The story of Juno and Alcmena is excellently given in Ovid's Metamorphoses. It always seems to me that the tales of Ovid are, for the most part, rather wearisome, but this one goes along finely and is full of movement, and Rabelais must have enjoyed it thoroughly, for, as Tilly says, alacrity and swift motion are important elements in Rabelais's imagination (4).

Juno was jealous and she had a right to be, for Jupiter was an old rip. The natural result of his little affair with Alcmena was a son, and Juno, powerless to do anything against Jupiter, took her revenge on the lady, and seated herself with her hands clasped over her knee chanting charms before

the house in which Alcmena was in labor. A red headed servant girl, who was passing in and out, swiftly correlated the presence of this tragic looking lady with the prolonged and ineffectual labor pains of her mistress in the house, and she thought of an expedient. Coming out with a pleasant smile, she begged her to cheer up as the birth had just terminated fortunately. It appeared that it was for Juno the psychological moment when she was wholly absorbed in the charm, and this news caused her to jump up and to fling her arms in the air. This indeed broke the charm, and Hercules was promptly born, whereat Juno was so outraged at the trick played upon her by the red headed servant girl that she sprang at her and, catching her by her prominently flaming top, she dragged her around on the ground in the front yard of the house, and finally turned her into a weasel with the curse that, thereafter and forevermore, she and her descendants should bear their offspring through the mouth instead of, as an obstetrician would say, *per vias naturales.*

There are some other touches in Ovid's account which are medically interesting. For instance, Juno sat with her left knee prominence (Latin, *genua,* Greek, *gona,* an angle) placed in the right *poplys. Poplys* is the real Latin name from which the medieval medical term, popliteus, is derived. It is here interesting to note that, as a contribution to obscurity, our anatomists have given the epithet, popliteal to two distinct regions, one involving the soft parts of the hollow of the knee, and the other, quite distinct from this, and well removed from it, to the space on the posterior aspect of the lower extremity of the femur. Major George F. Shiels, while acting as expert witness, once used this ambiguity cleverly to confuse a lawyer who was questioning him.

THE MEDICAL FINGER

The youthful Prince Gargantua had a ring made of four different metals on the left medical finger, and one made in a special shape on the right (5). It appears that the finger we now call the annularis was then also called the medical finger (*digitus medicus*) because the ancients were accustomed to spread out their ointments with it, and the form in which a procedure was carried out had then a vast importance. This finger had also an anatomically sentimental signification, as M. Pector says that it was on the annularis that the bride wore the conjugal ring, because it was believed that a vein originating there ran directly to the heart (6).

Also when Panurge consulted the Sibyl of Panzoust in regard to his marriage, he advanced toward her with a profound reverence and placed on her medical finger a fine gold ring, in which was a toadstone of Beusse, magnificently set (7). This he did to ingratiate himself with her, so that he might receive a happy vaticination. Everyone knows of his bitter disappointment, but in the matter of the ring, he behaved like a perfect gentleman. Although he got worse than nothing in return for his liberality, he retired without making any effort to reclaim his property.

Besides the medical finger there was also *le maitre doigt,* the master finger, which was the thumb, as being the strongest of all (8).

SCRATCHING THE HEAD

A head free of pediculi is a recently acquired luxury in the world's history. Rabelais seems to have had a special contempt for those who affected a sort of dandified delicacy by scratching their head with one finger (9).

In Rabelais's day the fingers had still another medical significance; they played an important part in graduation exercises. In conferring the degree of doctor of medicine, after the candidate had taken the oath, the president of the faculty delivered a brief exhortation, then took up a square topped hat, traced with it in the air the sign of the cross, and put it on the candidate's head. Then with two fingers of the right hand he gave him a light blow on the head, and then the accolade. This blow with the two fingers was called the *soufflet,* and signified that from that moment on the recipient became a new man, and that this was the last insult he would be called upon to endure. It was a ceremony such as this, modelled on the one conferring knighthood, that undoubtedly inducted Rabelais himself into the ranks of the medical profession at Montpellier in the year of our Lord 1530.

Another trick was to comb the head with Nature's own comb, the four fingers and the thumb, like a certain professor whom Rabelais named. This was a great saver of time, especially in the amenities of life, and Rabelais says that such trainers of youth asserted that for their pupils to comb the hair in any other way, to wash or to clean themselves was to lose time in this world (10).

Cleanliness, however, really expedites work, and Ian Hay relates that, in the English army on the Flanders front, the rule that the men had to be cleaned up and shaved by ten o'clock each day had to be strictly enforced, or all other work fell behind.

In another situation Rabelais speaks of scratching to signify ennui (11). Pantagruel and his companions were at sea in a sailing vessel during a dead calm. The only motion was the lazy rocking of the ship in the roll of the ocean. Pantagruel was sleeping with a Greek book in his lap; Epistemon was taking an observation of the sun: Friar John was in the kitchen looking after the roasts and the fricassees; Panurge was blowing bubbles with a pipe; Gymnaste was whittling toothpicks; Carpalim was making a toy windmill; Eusthenes was beating the devil's tattoo on the breach of a cannon; Xenomanes was repairing an old lantern; Ponocrates dreaming dreams, tickled himself to make himself laugh, and scratched his head with one finger. Suddenly Friar John appeared in the midst of all this drowsiness shouting, "How would it be as a pastime to have a drink?" Instantly the scene was changed, and everyone took on a Rabelaisian activity.

In another situation, the Queen of Entelechy (the Kingdom of Quintessence), who used to cure all disease with a tune on her wonderful organ, on receiving no answer from either Panurge or Pantagruel when she addressed them in the "hifalutin'" language natural to her, construed their silence as being either Pythagorean or Egyptian. Egypt was at that time the workshop of fine, wiredrawn philosophy, where the natural mode of communication re-

duced itself to biting the nails and scratching the head with one finger (12).

There are other references to the fingers, such as licking the fingers when anything good was eaten (13), a gesture much more frequent then than now, because of the relative scarcity of both forks and napkins. Then, too, there are the eloquent fingers (14) much more frequently encountered among the southern Europeans than among us of the more stolid north.

Of course, we now know many things about the human fingers with which Rabelais was wholly unacquainted. For instance, he did not know anything about glossy fingers, or about Dupuytren's contraction, or about the drumstick fingers associated with bronchiectasis, or about the clumsy fingers of myxedema, or about the tapering fingers of the lymphatic diathesis, and the equally tapering fingers of the solid edema of leprosy. Our knowledge of the hand in syringomyelia, Morvan's disease and sclerodactylia has also grown up since Rabelais watched his fellowman with such knowing eyes in the beginning of the sixteenth century.

He must have known about the tremulous fingers of palsy, and he often must have seen the clawed hand, *la main en griffe,* of leprosy during his service in the hospital at Lyons, but he does not mention them.

Contributors to the Science of Medicine

JOHN HUNTER

John Hunter, the Scotchman, was the most conspicuous pioneer in the study of comparative anatomy. The following notes dealing with parts of the career of that really great man are mainly gathered from the Hunterian oration delivered at the Royal College of Surgeons of England on February 14, 1923, by Sir John Bland-Sutton, president of the college, and which have been published recently in book form.

John Hunter was born at the farmhouse Long Calderwood near Glasgow. The house bears a tablet to the effect that he was born February 13, 1728. In his lifetime the birthday was kept February 14th, and the college drinks to his memory in "solemn silence" on the fourteenth. John or Jockie, as he was called at home, the youngest of a family of ten, petted by his mother, his father died in 1741 aged seventy-eight, disliked school and hated books. He preferred to lead an out of door life, looking after nests, insects and animals, while his brothers received the same education as country gentlemen. At the age of seventeen he spent some months with a brother in law, a timber merchant and carpenter in Glasgow, and his mother noticed that "the lad showed neatness of hands and quickness of perception in anything that regarded mechanism. As Sir John Bland-Sutton points out, it is instructive to consider how the farm life fitted John Hunter for his subsequent career. The practical surgeon is a craftsman: Greek and Latin are useful to him for polish, but think of the natural knowledge a smart boy can collect on a farm about the sowing, sprouting and ripening of crops, the breeding of animals, gelding of colts, spaying of pigs, caponizing of cocks, fattening and slaughtering of animals for food, farriery, shoeing and doctoring of horses, observing the wild life in ponds and ditches, fields and hedgerows, trees and heather. In the village he can watch the wheelwright, smith, tinker, glazier, cobbler and cooper, all experts with simple tools. Practical knowledge of this kind was useful in that state of life into which William Hunter, his brother, called him. At the age of twenty John Hunter came to London with the object of assisting his brother William, who had a school of anatomy at the back of his house in Covent Garden. John showed uncommon skill in dissecting, and worked hard. Human anatomy appealed to this uncouth Scot, and William Hunter moulded John's and "bred him to anatomy" in its widest significance with astonishing results. It is easy to understand that the rough, unschooled, apparently idle, Jockie Hunter when introduced to the dissecting room, became deeply interested in the structure of the human body and found it an absorbing study. Verily the gunpowder of genius is stored in many brains but it needs a match. Hunter studied anatomy in the winter and surgery in the summer. While engaged in the routine of dissecting and teaching he developed a taste for comparative anatomy, which became an absorbing passion.

In 1760 a force was sent from England to take Belleisle, an island near the mouth of the Loire. Hunter applied for an appointment with the expedition and served as staff surgeon. Belleisle was a country new to him in flora and fauna and he had no knowledge of marine zoology until he landed on this island which afforded him access to barnacles,

sea anemones, sea stars, sea nettles, sea cucumbers, sea squirts, sea urchins, squid, huge spider crabs, tunnyfish and he made the best of his opportunities. He next went with a British army to Portugal, where he studied botany and geology. On the conclusion of peace Hunter returned to London a staff surgeon and deputy purveyor on half pay. He took a house in Golden Square and started to practise. His half pay, probably half a guinea a day, helped to pay the rent. He opened a room for dissecting, made teaching preparations and while waiting for patients taught human anatomy for capital and comparative anatomy for interest. The classes were neither large nor lucrative, for he was not a good lecturer.

In 1765 he bought the lease of three pieces of land at Earls' Court, Kensington, built a house, established a small menagerie, and made observations and experiments. Leopards and jackals lived in the den, buffaloes, stallions, sheep, goats and rams occupied the stables. A mulberry tree furnished leaves for the silkworms, and St. John's wort supplied pollen for bees. There was a pond for ducks and geese which laid eggs for the table and for embryological studies. He made observation hives for the bees, discovered that their wax was a secretion, and left some excellent notes on the relation of vegetable to animal fat. With the aid of Ramsden's delicate thermometers he discovered the significance of the terms hot blooded and cold blooded animals.

JOHN HUNTER

In 1787 Hunter read a paper before the Royal Society on some observations "tending to show that the wolf, jackal and dog are all of the same species." The picture of Hunter accompanying this article is from a portrait painted by his brother in law, Robert Home, which now belongs to the Royal Society and which is the frontispiece of Sir John Bland-Sutton's book. The old dog in the picture is supposed to be the offspring of a half bred wolf bitch and an English mastiff.

The fame of Hunter is imperishably preserved in his wonderful museum now housed in the Royal College of Surgeons Building in Lincoln Inn Fields. According to Sir John Bland-Sutton, this museum owes its origin to the peculiar conditions under which medical education was carried on in London in the eighteenth century. Schools of anatomy were private ventures. It was necessary for the surgeon who owned and managed the school to illustrate his lectures with skilfully prepared specimens. Hunter made many preparations for his brother and some exist in the Hunterian Museum at Glasgow. But when he returned to London in 1763 he brought with him specimens of natural history from Belleisle and Portugal and these formed the nucleus of the collection for illustrating comparative anatomy. As Sir John Bland-Sutton says, it is a fair inference that the specimens were collected to subserve teaching purposes directly connected with his lectures, but it grew and widened until it became a museum that could be regarded as a discourse on the human body in relation to the animal kingdom. Gradually its founder's ideas expanded, and he conceived that it should be an ample illustration of life exhibited in the vast chain of organized beings, living and extinct, by a display of the various structures in which the functions of life are carried on. In 1783 he took premises in Leicester Square and built his famous museum. Sir Joshua Reynolds lived in the square, and the two men subsequently helped each other to what artists jokingly call immortality, one as subject, the other as painter. The famous picture by Reynolds of Hunter is the most cherished possession of the College of Surgeons.

On the death of Hunter his executors, Matthew Baillie and Everard Home, with rare judgment, retained the services of the former curator, William Clift. He had no books, so he read and made extracts from Hunter's manuscripts. The transcripts were made from some of the notes afterwards destroyed by Everard Home. They were published by Owen under the title *Essays and Observations* in 1861. For seven years Clift received seven shillings weekly and meekly as wages. In return for these sources he became the first conservator when the government bought the collection and intrusted it to the College of Surgeons in 1800.

The museum contains in orderly array, specimens, big and little, of every living thing Hunter could secure. Shrimps and sharks, humming birds and ostriches, shrews and whales. Of the human kind, dwarfs and giants. The fame of Hunter was such that new or rare animals were brought to London for his opinion. When John White returned to England in 1790 from New South Wales, "the nondescript animals of that settlement"—kangaroo, potoroo, tapoau roo, and the like were handed to Hunter for investigation. The museum is now so rich in specimens illustrating the anatomy of vertebrates, living or extinct, normal or abnormal, that practically every discovered specimen is there represented. So far as embryology is concerned the collection of malformations in the museum is the finest and most comprehensive in the world.

Hunter took keen interest in monsters not from curiosity but from the scientific viewpoint. Hunter clearly recognized the importance of studying the developmental stages of animals. Hunter studied the horse carefully both as an anatomist and a surgeon. Hunter helped to found the Royal Veterinary

College of England in 1791, he was a vice-president and with Cline, a well known surgeon of the time, served on the committee that approved of the appointment of Vian St. Bel as the first professor of the college. St. Bel died in 1793, probably from glanders. His early and unexpected death led to some difficulty, and Hunter, in order to help in the emergency, arranged for the students to have admission to the lectures of the leading teachers in the hospital. Hunter made a collection of whales and when he died in 1793 and for many years afterwards, his skeletons of whales were the only examples existing in a museum in England.

Hunter was one of the first collectors of fossils on a large scale in England and it is one of the romances of science that the discovery of the collection by Richard Owen induced that wonderful man to forego practice and bend his great intellect to comparative anatomy, paleontology and zoology. When Owen started to practise as a surgeon near the College of Surgeons, Abernethy, the great surgeon of the day, concerned at the neglected condition of Hunter's museum prevailed upon his old pupil Owen to assist in cataloguing it. In this way Owen became acquainted with Clift, the conservator, and obtained access to the collection. A few years later he married Clift's daughter, was gradually weaned from practice and devoted himself to comparative anatomy. While busy with the catalogue he unexpectedly found Hunter's store of fossils. Startled by the number and variety of the specimens he began to work on them seriously. He dissected the bodies of animals to enable him to study fossils and became essentially a paleontologist revelling in the reconstruction of extinct animals. The museum contains reconstructed skeletons of huge ground sloths; the gigantic armadillo with an "osseous coat in compartments," and a huge bird, the moa, towering above them all. Skeletons of sloths and armadilloe turtles and crocodiles, with ostriches and emus, stand in rows, demonstrating the truth of Owen's deductions. It was due to Hunter's fossils that Owen turned his attention to paleontology and inspired interest in the prehistoric animals which once moved on the face of the earth.

Hunter was a man far in advance of his time and had to contend with detraction, envy and prejudice as all such men have to contend. That his views were farseeing is being proved at the present time, if such proof were needed by the establishment of chairs of comparative medicine at universities and medical schools and by the full realization of the medical profession that much can be learned concerning human diseases from those of animals and that in order to discover the causes of many diseases medical and veterinary investigators must work in cooperation. A lesson may be learned from the life of Hunter, namely, that it is unnecessary for successful original research that a man should be well read or even well educated. Long schooling may not only tie down and hamper the play of genius but does not afford the opportunity for giving genius the widest scope. If Hunter had not been allowed to run more or less wild pursuing his own bent amid natural surroundings his intellect would not have blossomed so luxuriantly. Education tends to curb and narrow the inborn powers of the mind and in some instances stifles them entirely. John Hunter's works live after him and in his museum he has left monumentum dere perennius. His influence is an inspiration to the surgeons of today.

The Symbolism of the Goldheaded Cane.—Dr. Isador H. Coriat (*Annals of Medical History,* March, 1924) introduces his article by referring to the book entitled *The Goldheaded Cane,* written by Dr. William Macmichael and published in 1827. The cane, the history of which is told by Macmichael, and later by Dr. William Munk, is still preserved in the College of Physicians in London.

Historically the physician's cane is linked with the wig and ring as symbols of deep learning, wisdom and power. It is doubtless related in symbolic meaning to the herald's staff, the caduceus of Hermes, the wand of Æsculapius, the sacred wands of primitive peoples, the mystic wands of fairy tales, the staves of constables and sheriffs, and the phlebotomist's staff. Jeaffreson suggests that possibly in ancient times the physician's cane and the surgeon's club were used actively. For centuries fustigation was believed in as a sovereign remedy for bodily ailments as well as moral failings, and a beating was prescribed for ague as frequently as for stealing. Such customs may have been merely incidents in the history of flagellation, into which there enters strong sadistic and masochistic components.

The physician's cane was generally smooth, of moderate weight, and with a gold head in the form of a knob. Gold once was supposed to have medicinal properties, but the desire to make a good appearance on the part of the physician was probably the stronger motive. Often the head was hollow, and in the cavity it was the custom to carry some drug. A mystery about it was thus created in the mind of the people, some of whom believed that the head of the cane was the dwelling place of a familiar spirit which gave the owner extraordinary powers. The symbolism, therefore, is twofold: in the first place, the cane was a bit of magic, a charm, a sort of omnipotent instrument which had power over evil; second, it was the symbol of the office of the physician himself, like the caduceus, signifying that the owner has medical power and authority, is omnipotent in his calling. Gold was also the symbol of the sun, the all fertilizing divinity, Apollo, the father of Æsculapius. In alchemy, male activity is derived from gold, female from silver.

In summarizing his article, Dr. Coriat writes: "Thus the goldheaded cane became a sort of symbolic carrier of the power of the physician or the immortal transmitter or bearer of power as it passed from one physician to another. Historically it was emblematic of the physician's profession but beneath this there was a hidden symbolism, whose meaning stretched back to the beginnings of medicine in magic and thus unconsciously betrayed the secret of therapeutic power. Such transitions from literal meaning to veiled symbolism are very frequently encountered in the development of civilization and culture. To cite only one example of these age old mysticisms, we have the throwing of rice at a newly married couple which symbolizes fertility."

LAUGHTER

The laugh is said to be one of the sign manuals of the intelligent thinking animal; no one ever saw a true laugh on the lips of a domestic or wild animal. Apes grin and dogs have been taught to contort their lips into the semblance of a laugh, but no sound is forthcoming and its similitude to the human mode of exhibiting emotion, generally pleasure, by the sound termed laughter is indistinguishable. While then it may be allowed that laughter is a human gift, its origin is a question of scientific interest. Great men and ordinary individuals have argued and theorized as to the nature and purpose of laughter without completely understanding or explaining it.

In a treatise published last year Professor Greig showed that like love, laughter possesses a special and a general significance. Laughter is of various kinds, as hysterical, spiteful, satirical, Rabelaisian, Falstaffian, petulant, good natured and so on. To some extent a person's laughter reveals his character. The villain does not or, at any rate, should not have a hearty genial laugh. Mr. J. C. Gregory has brought out a book recently, published by Kegan Paul, London, dealing with the nature of laughter. He points out that laughter expressing the pure comic perception of the ludicrous, the source of the most highly civilized laughter, is the most difficult to analyze.

In attempting to define the real root of the external signs which accompany and express the mental perception of the laughable, he says that all laughter contains predominantly an element of relief, and leaves the impression on his readers that in his opinion the beginning of an understanding of the subject may be made from this point. The most primitive expression of a laughter provoking act is tickling, and Mr. Gregory's analysis of this phenomenon may be used as a foundation on which to build an appreciative consideration of the higher forms of laughter. According to Gregory the laughter which is aroused by tickling is due to the tickled person instinctively reacting to the touch as though it were a threat of bodily harm, and almost, at the same time, perceiving that the fear is unwarranted. The laughter does not arise from the sense of the ludicrous in this situation, though such a secondary or civilized laugh might be grafted on to the first, but from the physiological changes resulting from the mental apprehension of the fact that there was no danger.

The physiological process is explained as follows: "The call for action, against the threat, with which the situation resulting in laughter begins, increases the sugar in the blood. This sugar, and the other associated secretions, supply an extra source of energy. When action is called off, this extra store of energy producers would remain in the body, and become, since unrequired, waste products. These waste products would clog the body, which would be like a fire with too much fuel. Laughter, therefore, Crile suggests, substitutes for action by the body action of or in the body, and thus consumes the energizing secretions."

This explains the feeling of physical wellbeing which accompanies laughter, the excess energy being expended within the body, and it also accounts for the severe exhaustion which accompanies prolonged laughter. It is when the primary impulse to laughter is split up in the complications of social life that it becomes difficult to give a rational explanation of the various sources of laughter. Civilization and what may be termed refined society have had great influence on laughter. We no longer laugh at deformity and, as a rule, withhold the laughter which would inflict pain, but the nature of laughter remains the same. Society has moved in the direction of Hobbes's saying, "Laughter without offence must be at the absurdities and infirmities abstracted from persons." Which is to say that satire has become impersonal. However, the satirical laugh is still the expression of relief which is felt when a hostile idea is vanquished or made less powerful by ridicule. This is the primitive origin of laughter in a situation which has engaged the energies of the organism in a struggle against extinction and is the physiological reaction of the organism to gain relief and is still the function and justification of the laugh even in the most highly civilized circles. Laughter is an outlet for emotion, a safety valve whereby superfluous steam is blown off.

GARBAGE DISPOSAL BY THE BECCARI PROCESS

The Beccari process of garbage disposal, developed and used only in Italy, reduces garbage and other organic wastes by bacterial fermentation in closed cells. J. Waldo Smith, consulting engineer of New York city, contributes an interesting article to the *American Journal of Public Health* describing the main points of the process.

The Beccari process was developed through a long series of experiments by its inventor, Giuseppe Beccari, of Florence, who conceived it as a method for conserving manure for farms by fermenting the or-

ganic matter in closed cells. In the course of the work, about forty different forms and sizes of these cells were employed. The resultant product is humus, valuable as fertilizer. As now developed, the cell for municipal use is nearly cubical in form and contains about twenty-five cubic yards. The cells are built, back to back, of masonry, with a flat, reinforced concrete roof, in which is a charging hatch. On the side is a door for discharging. Since it is most important that the entire charge be aerated, so that the bacteria may work, a grating at the bottom supplies drainage and ventilation, and flues and air-passages around the side walls aid in this way. The ammonias formed by the process escape through a hole in the roof and are received in a tower, where they come in contact with absorbent earth, and an appropriate salt. Ferros sulphate is commonly employed, with the production of ammonium sulphate as a byproduct. Regulation of temperature and active propagation of bacteria through distribution of the air supply, according to the principles demonstrated by Pasteur, do the work. Florence, Italy, uses 208 cells to dispose of the garbage of the city, with 250,000 population.

When delivered, the garbage is dumped into the court between the row of cells and gone over for materials of commercial value. The cells are then filled with what remains. The first step in fermentation is to increase the temperature to 140° F. or more, and this is accompanied by the development of vast numbers of bacteria. Numerous experiments have been made to discover the action of the cells upon the microorganisms of typhoid fever, cholera, scarlet fever, trachoma, anthrax, etc. It was found that even the most persistent, such as anthrax, were completely destroyed. The larvæ of flies, fleas, and other parasites also were destroyed, and the germinative power of seeds checked. Bones emerged clean, with even the marrow eaten up by the bacteria. The bodies of dead animals were completely reduced, all that remained being a slightly humid, entirely odorless mass. The fermentation is finished in from thirty to thirty-five days. The fermented mass retains for a long time its heat and new heat is generated, as in manure.

After fermentation is completed, the product is stored in a large shed, where it stands for from five to fifteen days. Then it is cast through screens from one to several times, according to the type of fertilizer desired. Sometimes the product is used without screening. The writer says that he interviewed the director of the Italian National Agricultural Station, who stated that the Beccari product had been used solely for two years and had proved entirely satisfactory. Among other Beccari plants in operation in Italy, is one at Naples with 450 cells. As a unit system, writes Smith, it would be entirely practicable for any interested community to prove with moderate expense the effectiveness of the process to meet the prevailing conditions before adopting this method of organic waste disposal.

MIGRAINE

Migraine is a fairly common complaint of all civilized countries; it is hardly an affection which troubles members of a primitive race, as after all it is partly due, perhaps largely due, to abnormalities of the nervous system. Also, as Dr. F. G. Crookshank in a lecture delivered at the Northeast London Postgraduate College on February 8, 1924, pointed out, it is a subject of intrinsic importance and the migrainous not only themselves endure a vast amount of suffering but entail much discomfort on those associated with them. Moreover, it is a subject to which scant attention has generally been given and too frequently dealt with superficially and inadequately. However, this fault has been remedied or is in the process of being remedied, and up to date textbooks give to migraine the attention which its importance deserves.

An excellent description of migraine was given in a little book written by Dr. Joseph Collins, of New York, some years ago entitled *The Way with the Nerves,* in which its nervous manifestations were adequately dealt with. One of the clearest accounts ever given of its etiology is that by Dr. James Collier in Price's textbook of the *Practice of Medicine.* It is pointed out that many theories have been advanced as to the nature of the malady. It has been held to be the result of a temporary condition of intoxication from digestive, metabolic or internal secretory disorder, which recurs periodically. Collier thinks that there is little evidence in support of this view, for it is a common experience to meet with patients who had restricted their diet to an amazing extent to avoid what they deemed were "bilious attacks" with the result that the migraine had become aggravated. Neither has treatment directed against such errors had the slightest effect in benefiting migraine. Local spasm of the cerebral arteries has been advanced as the cause of the phenomena, on the grounds of the pallor and construction of the vessels of the skin and retina, which occur during the attacks.

This theory is adequate to explain the varying nature of the attacks in some cases, at one time a headache, at another teichopsia and hemianopsia without headache, at another time aphasia or hemiplegia or sensory aura without headache. However, as Collier states, it is entirely hypothetical and breaks down utterly as an explanation of the severe and

lasting ophthalmoplegia, which may accompany very severe attacks, and will hardly explain those cases in which the headache lasts for weeks or becomes continuous. Attention also may be drawn to the fact that pallor of the surface vessels is the constant accompaniment of every severe vestibular disturbance, and many sudden changes in blood pressure, as in seasickness, etc. It has been held that migraine is due to a functional disorder of the cerebral cortex in the way of combined inhibition and discharge, akin to epilepsy, solely on the grounds of the nature of the visual phenomena and of the sensory auræ, and that migraine occurs occasionally in epileptics. Undue prominence has been given to the importance of refraction as causes of migraine. Certainly, such errors when existing are likely to cause vestibular upset and therefore may be exciting causes of an attack and should in all cases of migraine be corrected.

The majority of the subjects of migraine have no such errors of refraction, nor has the correction of such errors ever cured migraine. Spitzner examined the brains from several cases of long standing and severe unilateral migraine, and found in each case a unilateral distention of the lateral ventricle corresponding with the side of the headache, and an anatomical condition of the choroid plexus in its relation to the foramen of Munro, which might easily cause plugging of that foramen from conditions of turgescence of that plexus. He attributed the attacks of migraine to temporary unilateral hydrocephalus, from temporary plugging of the foramen of Munro. His specimens are in the museum of Johns Hopkins University.

This theory is the only one based on pathological evidence, and in the opinion of Collier will explain migrainous ophthalmoplegia, for as he argues some very gross anatomical disturbance must take place within the skull to account for such severe and lasting paralysis of peripheral oculomotor nerves. The subjects of migraine are otherwise quite healthy and robust and strong and are nearly always of an active, capable and intelligent type. According to Crookshank not a few distinguished medical men, and many celebrated physicists, astronomers and philosophers have been migrainous, and have left us illuminating accounts of their sufferings. Crookshank is inclined to attribute the condition largely to the psychological situation and in his view the sex problem runs like a scarlet thread throughout and both male and females are impressed with or conscious of a personal or sex superiority. The migrainous woman resents all suggestions of feminine inferiority, which perhaps does not show that she is conscious of superiority but rather that she is unconsciously fearful of inferiority or of being considered so. The migrainous male takes male superiority for granted. Crookshank argues that migraine is a repression state, a repression of "rage and humiliation" felt in face of some problem, practical, ethical, or intellectual, that appears insoluble. The brainstorms of the migrainous, and that of the neuralgic, are defense and flight and excuse mechanisms, analogous to those which during the war, were found to be exhibited in face of physical danger.

The peculiar character of the paroxysm in each case is determined by the organ inferiority or state present. Taking the view Crookshank holds that migrainous people should be treated by psychological methods, it is interesting to know that Plotinus, the Neo-Platonist, held that cure of bodily disorder must depend upon adjustment of the unconscious mind.

MENTAL HYGIENE

Mental hygiene is of the first importance and especially in these times when children are born in immense numbers with an inherited unstable nervous temperament. Civilized life and life in cities in particular tend to produce a nervous stock with various inherited susceptibilities to disease of body or mind. The war and its aftermath, in Europe in particular, too, have intensified the tendency and it is astonishing to note the multitudes of persons obviously unstable physically and mentally. While inherited taints and susceptibilities are responsible for a great deal of the nervous manifestations witnessed at the present time, the life of large modern cities is not best calculated to benefit this state. On the whole, it may be stated that, probably, there has never been in the history of the world a period when nervous affections were so widespread.

In the first instance, in order to have a sound mind in a sound body an individual should be born healthy, and this good start is denied to many because they have inherited from their immediate progenitors an heredity taint or from them or their more remote forebears a predisposition to certain diseases or conditions of ill health. There are a few diseases which may be transmitted and which may doom the offspring to nervous affections of a serious character and which in the view of many authorities should preclude matrimony and even parentage. Children born of such stock are handicapped to a greater or less extent from the beginning but their lot can be greatly improved by paying scrupulously careful attention to their hygiene generally and to the hygiene of their nervous system.

The nervous system may be affected profoundly by the consumption to excess of toxic materials as, for instance, alcohol and other narcotizing drugs. The consequence of too great an indulgence in nar-

cotics is exhibited in the offspring in the form of an unstable nervous system. In such cases hygiene can play a restorative or strengthening part and suitable environment during youth can do much towards rehabilitating a nervous system damaged by the effects of heredity. As is pointed out in an article by Dr. J. W. Courtney which appeared in the *Boston Medical and Surgical Journal,* March 27th last, the work of physical salvage of the victims of an hereditary adynamic nervous system must be begun while they are in the formative period of life.

In the upbuilding and maintenance of vigor of the nervous system, the problem of diet looms large, while in this country, at any rate, it is beginning to receive the scientific study its importance deserves. At home parents are often kind to their children only to be cruel; that is, they allow them to eat quantities of food which has little or no nutritional value. For example, children frequently consume candy to such an extent that they contract the candy habit. In this way they injure their digestion, ruin their teeth and plant seeds of gastrointestinal troubles which come to fruition in adult life and henceforth are the bane of their existence. Children of this type are generally possessed of an ill balanced, nervous system with morbid tendencies, one outlet being an unrestrained appetite. Proper upbringing is more than half the battle with the child whose parents or ancestors have handed down to him a defective nervous system.

Before leaving the subject of hereditary nervous affections, it may be as well to call attention to other diseases, which by flooding the system with poisons are apt to transmit to another generation a susceptibility to the same diseases together with a somewhat abnormal nervous system. Rheumatic affections come within this category, and the chronic forms most emphatically. An individual with chronic rheumatism, and there are many comparatively young persons with that type of disease, is poisoned throughout his system, and the diathesis is or may be handed down to the children. In all toxic states of the body the nervous system is more or less involved. In the case of children then born ill balanced from the point of view of the nervous system great care must be taken to bring them up in such a way that their lack of stability is corrected as far as is possible rather than accentuated. One habit which must be always encouraged and never allowed to fall into default is that of keeping the functions of elimination and excretion at work freely. By following this rule the waste food products are not allowed to remain sufficiently long in the system to poison it and physical and nervous vitality lowered in consequence.

In proportion as the physical powers increase so the nervous system gains stability. The object therefore in attempting to overcome inborn nervous defects or traits is to feed and bring up those affected in the manner best suited to the individual case, the basis of training, however, being the leading of a regular wholesome life so as to store up a goodly reservoir of nervous energy for use in the future. To dissipate nervous energy in childhood and youth, as many American children and youths are allowed to dissipate it, means a premature decay of the vital powers. Conserve this energy wisely and a healthy life and a green old age may be anticipated.

THE EXCEPTIONAL PATIENT

Every patient is, to an extent, exceptional—at least, different—and it may well be borne in mind that the new patient—the one with whom we have had little or no experience previously—may be a different one, especially from the therapeutic viewpoint.

This has been most strikingly and sadly illustrated recently in a case reported by Bazin in the *Journal of the Canadian Medical Association.* The patient was a boy of fifteen years, apparently much like other boys, and the ailment was common enough—constipation. The treatment was not so common, but the drug used was seemingly harmless—two enemas a day consisting of six cups of water containing six teaspoonfuls of boracic acid. These enemas were followed on the first day by bowel movements, but on the second day by frequent vomiting, and on the third day by a continued vomiting and by a general skin eruption.

The enemas were stopped on the fourth day, the rash began to fade, and the vomiting ceased. On the sixth day two more enemas were given, with a return of the symptoms. The child grew steadily worse and died on the eighth day.

Whether the resumption of treatment was brought about at the instance of the physician we do not know, but we have known a treatment to be persisted in from sheer insistence on favorite routine, which, in most cases, had seemed to be helpful, but which, in the individual case, it was evident to an unbiased outsider, did more harm than good.

Potassium iodide is so commonly used and so often with benefit that we do not usually think it can be harmful, yet we have seen a comparatively robust man thrown into convulsions by a few ten drop doses in the treatment of syphilis, and death undoubtedly was due to a not large dose repeated after a few weeks' interval by another physician who had been warned of the patient's idiosyncrasy.

Anyone who has seen the dire results which may follow the ingestion of a fraction of a grain of quinine will ever after question his patient as to whether

he can take this drug with impunity. Nor can he be absolutely certain then, for a person may be sensitive one year, whereas he was not so the year before.

On the other hand, in a great many instances the physician fails to accomplish his desired end because he does not give a drug in sufficient quantity. It is always well to be on the safe side, but with patients whom we can study it is well to remember there are degrees of tolerance as well as of intolerance. As one distinguished teacher puts it, if a remedy is given, it should be given in sufficient amount to produce the results aimed at, no matter what the average dose may be. One should always be wary, however, in the case of the new patient and bear in mind also that there may be an idiosyncrasy for almost anything, also that in too large amount even sugar, salt, or plain water may be a poison.

THE VALUE OF THE DENTIFRICE

In these pages we have called attention to the extravagant claims which are made for the action of many dental pastes and powders. That they should have more than a momentary effect in changing the reaction of the fluids of the mouth, in digesting plaques or in reducing the bacterial flora, hardly needs to be pointed out. We have given them some credit, however, as cleansing agents.

Now comes a dentist of experience, Dr. Tishler, of Boston, and casts much doubt upon even this quality. In *Dental Cosmos* for May he points out that "immigrants who arrive in this country from the rural districts of some parts of Europe, where mouth hygiene is unknown, have beautifully clean teeth, but a few years of our city living changes this completely even when the toothbrush and paste or powder are adopted for toilet use. Caries also becomes the rule rather than the exception and is often accompanied by advanced peridontal disturbances from turgid inflamed gingivæ to rapidly developing pericemental disintegration and pocket formation."

"Would this indicate that the use of paste or powder is sufficient to keep the mouth and teeth in a state of health? Does the condition of the average mouth that we, as dental practitioners see constantly, bear this out? . . . Several years ago the writer became convinced that powder and paste were negligible as a factor in developing and maintaining good mouth hygiene, that no matter whether an alkaline or an acid dentifrice was used the resulting condition was equally unsatisfactory. . . ."

"Is it not time that we consider this problem of pastes and powders carefully and take some real steps toward improving the mouth hygiene of our patients? If the constant use of these agencies over a period of years will not produce better results than we see constantly, why should we not endeavor to find some thing or method that will?"

Tishler is of the opinion that, aside from the right diet, "the problem of obtaining and then maintaining good mouth hygiene does not concern any particular powder or paste, no matter what the ingredients may be, but is a question of mechanical application and thoroughness of brushing by the patient." The method he advises is "proper brushing faithfully carried out two or three times a day, plus a half teaspoonful of salt to a glass of water, and a thorough use of this solution as a wash after the brushing is finished."

Notwithstanding their possible ineffectiveness as cleansing agents, there still remains a field of usefulness for the dentifrice in the toilet of the teeth inasmuch as most of us are so constituted that the more elaborate and expensive a performance, the more willing we are to carry it out, while the good feeling and taste which a dentifrice leaves conduces to the simultaneous use of the brush. As for a hair tonic, its chief value lies in the fact that it causes us to brush oftener and more effectively, in proportion to the esthetic satisfaction it confers.

News Items

Medical School.—The new Medical College of the University of Rochester was recently dedicated, Dr. Benjamin Rush Rhees, president of the university, laying the cornerstone, and Dr. Edward Bright Vedder, of the Army Medical Corps, making an address.

Surgical Clinics.—Practical clinicoexperimental clinics will be held at the New York Homeopathic Medical College and Flower Hospital on the fourth Wednesday of each month—to include experimental demonstration of new surgical procedures developed at the Laboratory of Surgical Research and results obtained in studying different surgical problems.

Industrial Hygiene Reference Manual.—The Division of Industrial Hygiene of the State of New York has prepared for the use of physicians in New York State who are interested in industrial hygiene, a cross reference pocket manual on industrial diseases. A limited number are available, and physicians desiring a copy should apply for it without delay.

Electrotherapeutic Clinics.—Clinical demonstrations will be a feature of the annual meeting of the American Electrotherapeutic Society, which is to be held in New York September 9th to 12th under the presidency of Dr. Sinclair Tousey. The physiotherapy clinics of the U. S. Veterans' Bureau and of the Reconstruction Hospital have been offered for this purpose.

Veterans' Bureau.—A council on medical and hospital affairs has been appointed to aid the Veterans' Bureau in improving its service. Its first conference with General Hines and Dr. O. E. Cressman, Medical Director, was recently held in Washington. The council includes: Dr. S. S. Goldwater, New York; Dr. M. T. Macaachern, Chicago; Colonel R. U. Patterson, U. S. A.; Dr. W. C. Rapplaye, New Haven; Dr. Joel E. Goldthwaite, Boston; Dr. Frank Billings, Rhode Island; Dr. George W. Crile, Cleveland; Dr. Sidney I. Schwab, St. Louis; Dr. Thomas W. Salmon, New York; Dr. G. H. Kline, Boston; Dr. W. F. Lorenz, Wisconsin; Dr. George H. Kirby, Ward's Island, N. Y.; Dr. A. M. Barrett, Ann Arbor, Mich.; Dr. Douglas A. Thom, Boston; Dr. H. A. Pattison, New York; Dr. Roy Adams, Washington; Dr. Kennon Dunhan, Cincinnati; Dr. M. M. Davis Jr., New York, and Dr. Louis I. Dublin, New York.

New Home for Medical Society.—"The Mansion," on Colonial Road, has been purchased as a home for the Bay Ridge Medical Society.

Addition to St. Mark's Hospital.—St. Mark's Hospital, New York, is to be rebuilt, but in such a manner as not to interfere with its clinical activities. The buildings, when completed, will cost $1,250,000.

Flatbush Medical Society.—The following officers were elected by the Flatbush Medical Society: president, Dr. Samuel Fisher; vice-president, Dr. Stanley B. Thomas; and secretary, Dr. William F. C. Steinbugler.

College Discontinued.—The College of Dental and Oral Surgery, in existence since 1852, has applied for an order dissolving the corporation. The property has been transferred to Columbia University.

Victor C. Myers Goes to Iowa.—Victor C. Myers, Ph.D., has been selected as professor of biochemistry at the Iowa State University, and has also been appointed pathological chemist to the University Hospital.

American Electrotherapeutic Association.—The American Electrotherapeutic Association will hold its annual meeting September 9th to 12th, at the Hotel Pennsylvania, New York. All legally licensed physicians are welcome.

Medical Charity.—The largest single item, $1,257,000, and fully a third of the budget for the Federation for the Support of Jewish Philanthropic Societies in New York, was voted for medical care and medical social service.

Royal Society of Medicine.—Sir St. Clair Thomson has been elected president of the Royal Society of Medicine, London. He is an honorary member of the American Medical Association, and an Honorary Fellow of the American Laryngological Association.

Training for Tuberculosis Workers.—The National Tuberculosis Association, through a committee including Dr. Haven Emerson, Dr. Hoyt E. Dearholt, and Dr. Harry H. Hopkins, is planning a study of adequate training for tuberculosis workers.

Industrial Hygiene Institute.—An extension course in industrial hygiene for nurses will be given by Fordham University, at the Social Service School, located in the Woolworth Building. The course will be fifteen weeks in duration, and will begin September 30th. All registered nurses are eligible.

Palestine Medical Work.—Dr. Israel S. Wechsler, secretary of the American Jewish Physicans' Committee for the medical school of the Hebrew University of Palestine, will very soon leave for Europe and Palestine to supervise the beginning of the medical work. Dr. Henry Keller, of New York, has recently gone abroad, and before his return will deliver a series of postgraduate lectures on surgery at the University.

Tuskegee Hospital.—All negro control has been established at the Tuskegee Alabama Veterans' Bureau Hospital, thus ending a long controversy. Dr. Joseph H. Ward, of Indianapolis, formerly chief of the surgical service, has been appointed chief medical officer and commandant.

The United States Civil Service Commission announces an examination for junior medical officers, colored, for tuberculosis and neuropsychiatry at this hospital, salary $2,840 at entrance.

New Societies Organized.—A committee consisting of Dr. Victor V. Anderson, New York, chairman, Dr. Herman N. Adler, Chicago, Dr. Lawson G. Lowrey, Minneapolis, Dr. David M. Levy, Chicago, Malcolm A. Bliss, St. Louis, and Karl A. Meninger, Topeka, secretary, is engaged in the organization of the Association of American Orthopsychiatrists.

The Washington Psychoanalysis Society has recently been organized, with Dr. William A. White, president; Dr. Joseph C. Thompson, vice-president; and Dr. Lucille Dooley, secretary-treasurer. Membership is restricted to physicians, and is conditioned upon the presentation of a thesis containing a history of one case successfully analyzed by the applicant; the applicant himself must also present evidence of having been successfully analyzed.

The Massachusetts Psychiatric Society has been organized, with the following officers: President, Dr. Walter E. Fernald; vice-president, Dr. George M. Kline, and secretary-treasurer, Dr. Ralph M. Chambers.

Defense Test Day.—September 12th, the sixth anniversary of the Battle of St. Mihiel, has been designated by the President as Defense Test Day, and will be marked by the assembling of the Regular Army, the National Guard, and the Organized Reserves in their home communities.

Medical Reserve Officers at Carlisle.—A medical training camp has been in operation at Carlisle Barracks, Pennsylvania, for the past few weeks, the regular personnel being augmented by over a thousand men of the Medical Department, R. O. T. C. students, Reserve Corps Officers of the Medical Department, and the 104th Medical Regiment of the Maryland and Virginia National Guards. This training course is part of the preparedness plans of the Surgeon General of the Army for field service, and maneuvers were carried out under simulated battle conditions.

Society News.—The Maine Medical Association elected the following officers at its recent annual meeting: Dr. Fred W. Mann, Houlton, president; Dr. Joseph D. Phillips, Southwest Harbor, president-elect; Dr. Nathaniel M. Marshall, Portland, and Dr. Carl Stevens, Belfast, vice-presidents; and Dr. Bertram L. Bryant, Bangor, secretary.

The Massachusetts Medical Society has elected the following officers: president, Dr. Enos H. Bigelow, Framingham; vice-president, Dr. Ralph W. Jackson, Fall River; secretary, Dr. Walter L. Burrage, Brookline; treasurer, Dr. Arthur K. Stone, Framingham; librarian emeritus, Dr. Edward H. Brigham, Brookline; and orator, Dr. David Cheever, Boston. The one hundred and forty-third annual meeting of this society has recently been held.

The American Pediatric Society has elected the following officers: president, Dr. John Ruhrah, Baltimore; vice-president, Dr. Fritz B. Talbot, Boston; secretary-treasurer, Dr. Howard C. Carpenter, Philadelphia.

The Medical Society of Virginia, the Medical and Chirurgical Faculty of Maryland, and the Medical Society of the District of Columbia has elected the following officers: Dr. Howard Fletcher, Warrenton, Virginia; first vice-president, Dr. George T. Klipstein, Alexandria, Virginia; second vice-president, Dr. Thomas M. Foley, Washington; treasurer, Dr. Robert S. Lamb, Washington; recording secretary, Dr. William T. Davis, Washington; corresponding secretary, Dr. Joseph T. Foley, Washington.

The American Dermatological Association has elected the following officers: Dr. Howard Fox, New York, president; Dr. Andrew Porter Biddle, Detroit, vice-president; Dr. Udo J. Wile, Ann Arbor, Michigan, secretary-treasurer.

Personals.—Dr. Charles W. Gould, of New York, has been elected president of the National Eugenics Research Association.

Dr. Cuthbert Christy, the British physician who discovered the tsetse fly to be the carrier of the infectious cause of African trypanomosiasis, has recently been in New York, enroute to attend the Toronto meeting of the British Association for the Advancement of Science.

Dr. Julius Levy of Newark, director of child hygiene for the State of New Jersey, has sailed for England to represent the American Public Health Association at the English Speaking Conference on Infant Mortality, to be held in London.

Dr. Charles North Dowd, professor of surgery at the College of Physicians and Surgeons, has received the honorary degree of Doctor of Science at Williams College.

Two distinguished foreign visitors have recently been in New York, Dr. John C. Bramwell, Fellow of the Medical Research Council of Great Britain, and Dr. Karl Petren, professor of internal medicine of the University of Lund, Sweden.

Dr. Arthur E. Patrell, executive officer of the Boston Psychopathic Hospital, has been appointed assistant superintendent of the Sheppard and Enoch Pratt Hospital of Towson, Maryland.

Dr. William D. Haggard, of Nashville, Tenn., is president-elect of the American Medical Association for the coming year.

Dr. George C. Ruhland is to become the administrative director of the Milbank Fund health demonstration at Syracuse, New York. His resignation as health commissioner of Milwaukee is soon to take effect.

The Salpétrière Hospital

B. SHERWOOD-DUNN, M. D.
Paris

Salpétrière Hospital at Paris is one of the most celebrated hospitals in the world. It was created by letters patent dated July, 1653. The property covers 275,450 square metres, of which 34,635 are covered by buildings, the remainder being given up to parks, gardens and boulevards. It derives its

Fig. 1.—Front elevation of the Salpétrière Hospital today.

name from certain buildings incorporated in the original letters patent which were devoted to the manufacture of saltpeter. The property comprises a city in itself of five thousand inhabitants.

December 10, 1669, Louis XIV decided to replace the small chapel in the grounds by a church that should be proportioned to the extent and importance of the property. This edifice is in the form of a basilica composed of four naves extending on each side from a central dome which dominates the hospital from every point.

Fig. 2.—The Salpétrière Hospital in the seventeenth century.

In 1684 the prison of La Force was constructed in the hospital park for the detention of women and girls of bad character picked up from the streets and remained consecrated to this usage until 1792, when thirty-five women prisoners were massacred within its walls by religious fanatics. The building was then transformed into a retreat for the infirm and its name changed to St. Vincent de Paul.

The hospital known as the Hotel Dieu, in the square of Notre Dame Cathedral, always was and still remains one of the most beautiful hospital buildings in Europe. By a decree dated July 22, 1780, the admission of insane patients into this hospital was interdicted and the architect Payne was charged with the construction of infirmaries in the grounds of Salpétrière for the reception of these patients.

At the present time Salpétrière comprises forty-four buildings. January 1, 1924, the hospital contained fifty-nine insane, 2,642 aged and infirm and 3,249 patients.

The medical service comprises one resident doctor, five visiting doctors, one surgeon, twelve interns, twenty-seven externes, one chemist and five interns in pharmacy. The secondary personnel for the care of the different departments of the hospital comprises 1,009 men and women. There is a special school for defective children and idiots. The first school for the instruction of nurses was established April 1, 1878. The hospital laundry, which forms a part of this establishment, with a capacity for handling two and one half tons of linen a day. The hospital baths were visited by 57,241 persons during 1923. The hospital is supplied with reservoirs with a capacity of 1,800,000 litres of water and all of the hospital wards are furnished with Pasteur filtres.

Each service has its laboratory and that devoted to clinical teaching has a complete installation for bacteriology, histology, pathology, etc. . . . The hospital possesses an interesting museum. It possesses also a medical library of more than three thousand volumes, which is kept up to date. Two very celebrated paintings known throughout the world and sought by many visitors annually are found, one in the council chamber of the hospital, an allegory to the Roi-Soleil Louis XIV, and the other in the lecture room of the hospital by Toney Robert Fleury representing the celebrated Pinel removing the chains from the insane. There is also a life size portrait of the celebrated Charcot whose name and fame will forever form an indelible page in the history of this institution.

Shortly after graduation from the Paris Faculty, I became attached to the service of Prof. Charcot

Fig. 3.—The Salpétrière Hospital in the nineteenth century.

and translated his first pamphlet on hypnotism into English for publication in London, during which time I lunched with the family at his residence in the Bd. Saint Germain every Sunday. Charcot set aside Sunday as a day of recreation and at these Sunday lunches were gathered the leaders in many different walks of life. Here I met Paul Bourget, Eleanora Dusé, Arthur Meyer, Montesquieu, Capus and Bougereau, Bonnet, Melba; the master was particularly pleased when I brought with me Dr. William T. Lusk. Never shall I forget seeing Charcot and Gladstone walking in the shade of the magnificent trees of his garden.

HOME FOR THE AGED AND INDIGENT

There are no poorhouses in France and certain hospitals are designated to receive these people: Salpétrière is the largest single retreat in Paris for the aged, infirm and indigent. Its beautiful parks and gardens and magnificently shaded walks and boulevards form an Elysian retreat which makes the declining years of these unfortunates the happiest of their experience.

The unfortunates who become residents of Salpétrière are no sooner admitted than they begin to appreciate the benefits they are to enjoy, of a regulated life, three meals a day, with regular hours of sleep, in comfortable beds, furnished with white linen; regular days and hours for baths and fixed rules for general cleanliness, exercise and recreation.

During their residence they are freely permitted to leave the grounds Sundays, Wednesdays and Fridays from six in the morning to nine in the evening and at any day in the week, from noon until four P. M.

In 1891 there were placed in the Esquirol division forty beds for the reception of young girls and children, morally abandoned, in charge of Dr. J. Veisin. These unfortunates are sent into the school, others into the sewing rooms, laundry or other departments of the hospital work.

Foreign Correspondence

LONDON LETTER

(*From our own correspondent*)

London, *July 4, 1924.*

ANNUAL CONFERENCE OF THE BRITISH HOSPITALS ASSOCIATION

On June 19th last Sir Arthur Stanley, head of the British Red Cross, and president of the British Hospitals Association, presided at the fourteenth conference of the British Hospitals Association, which was held in Victory House, Leicester Square, London, W. C. The first paper read was by F. N. Kay Menzies. He stated that an adequate and coordinated scheme for the prevention and treatment of disease throughout the whole country should provide: 1, for the preservation of the best features of the present voluntary hospital system; 2, for adequate accommodation, equipment, and finance of the hospitals generally; 3, for the geographical distribution of hospitals so as to avoid unevenness and overlapping; and 4, for a closer relationship between voluntary hospitals themselves, between voluntary hospitals and the various classes of hospitals provided by local authorities, and between general practitioners and all the various institutions which treated the sick. Lord Hambleden said that one point to be borne in mind was whether, if grants were made, they would be likely to seriously affect voluntary subscriptions. They wanted to know what was likely to be required of the voluntary system in the future; what accommodation would be wanted throughout the country; and how best the voluntary system could take part in any scheme which might be devised; but it would be a great mistake to believe that the voluntary hospitals would not work in any general policy that the government or the country might decide upon. Lord Armstrong believed that what was wanted was a short Act of Parliament removing the restriction imposed by law on authorities subscribing to hospitals. Mr. H. M. Crouch moved a resolution to the effect that the time had come to make a careful, comprehensive and detailed survey and study of the hospital situation in Great Britain, and to formulate a coordinated scheme for the prevention and treatment of disease throughout the whole country. The motion having been seconded by Mr. C. E. S. Flemming, Bradford-on-Avon, Mr. Gilbert Shepherd, Cardiff, proposed that the Council should be requested to give careful consideration to the important points raised by Dr. Menzies, and to take such action thereon as they might deem desirable in the interests of the voluntary hospitals. Another motion followed by Mr. Arthur Griffiths, Ipswich, who suggested that they should ask the Voluntary Hospitals Commission to make further inquiries. The chairman thought that the association should make the inquiries, and not the commission. He suggested, therefore, the addition to Mr. Crouch's motion of the following words: "And that the council of the association be instructed to consider how the survey can best be made, and to give all the assistance in its power to any body that makes it." The suggestion was accepted, and Mr. Crouch's amended resolution was adopted.

TRAINING OF NURSES

Sir Wilmot Herringham, consulting physician to St. Bartholomew's Hospital and chairman of the council on registration of nurses, took as his subject the training of nurses. He pointed out that when he was young many ladies took up the nursing profession, partly, he supposed, due to the enthusiasm created by Florence Nightingale, but chiefly because it was the only means of earning a living which educated women could then pursue. At the present moment a woman might be a solicitor, a barrister, a doctor, a minister of religion, or even a member of Parliament. It was not surprising, therefore, that women did not enter upon a poorly paid and laborious profession such as nursing. Mr. John Barker Grimsby moved a resolution requesting the committee of the B. H. A. to consider the ruling of the General Nursing Council as to the number of medi-

cal beds, and also the medical cases, at present required to obtain their certificates. The motion was carried.

ENGLISH SPEAKING CONFERENCE ON INFANT WELFARE IN LONDON

Mr. Wheatley, British Minister of Health, gave the presidential address at the opening of the third English Speaking Conference on Infant Welfare at Caxton Hall, Westminster, London, on July 1st last. There were seven hundred delegates present, including representatives from British public authorities and voluntary institutions, governments and organizations in the oversea dominions, and health associations in America. Mr. Wheatley stated that maternity was the very source of the nation and good motherhood was essential to the welfare of the children. The majority of these children must be brought up by their mothers in their own homes. It was, therefore, of the greatest importance that the mothers should be sufficiently strong physically, and well educated and trained mentally, to make them the best mothers a nation could possess. Their duty was not to relieve the mother of her functions and duties but rather to train and help her to perform them satisfactorily. Nothing of a much more evil character crept into our national policy than the idea that any public organization could possibly take the place of the mother in a civilized community. The care of the mother was the first consideration for a conference of the kind which was being held. His department looked for good results from the school medical service which was now growing, and to the training which was given in the schools. Things would never be satisfactory until they had homes in which it was safe for children to be born.

He hoped that in the near future, as a result of the campaign in which they were now engaged, there would be an improvement in the midwifery services. The services of the midwife, and medical advice, should be available where it was required, and it should be the business of local authorities, or voluntary agencies, to see that when advice had been given that the means existed for making it effective. The care of the infant was an important work, and it was gratifying to find that there had been a fall in infant mortality during the past generation. In 1900, the infant death rate of England and Wales was 150 per 1,000, whereas in 1923 it was 69 per 1,000. It was true that there were black spots. While there was an average infant death rate of 69, there were certain areas, particularly in the poor districts of industrial centres, where the infant death rates ran into three figures. Mr. Wheatley emphasized the importance of making mothers familiar with welfare work. They had, he said, two thousand welfare centres in England and Wales. He hoped the time was not far distant when they would have a welfare centre within the reach of every woman, not merely in the towns, but in the villages.

Dr. G. F. Still afterwards presided and the subject of Education in Relation to Maternity and Child Welfare was considered. Colonel R. J. Blackham, M.D., read a paper relating to work in India, and said there was a quickening of the public conscience in that country of today, and that a definite movement was in progress to combat the social and semireligious customs which were responsible for the terrible dangers which had hitherto attended childbirth in India.

Dr. Ethel Cassie, of Birmingham, spoke on the training of midwives. She said the present high rate of maternal mortality and the high neonatal death rate among infants made it imperative to obtain early reform in midwifery training whether for nurses or doctors. Careful consideration, too, of early deaths in infants showed that little could be done apart from antenatal care and improved midwifery, and as long as the neonatal deathrate was unchecked it would be impossible to obtain a really satisfactory reduction of the infant mortality rate.

LETTER FROM PARIS

(From our own correspondent)

Paris, *May 25, 1924.*

Speaking under the auspices of the American Women's Club at the Union Interalliée, in Paris, Dr. George E. Vincent, president of the Rockefeller Foundation, chose as his subject An Adventure in Public Health and told of the fight against yellow fever. He explained that a League of Nations in Central and South America had been formed to banish yellow fever, and then traced the fight against the disease, which started during the Spanish War, when, under Walter Reed, four American physicians went to Havana to investigate the causes of yellow fever. They confirmed the opinion of Dr. Finley, a Scotsman, that the fever was transmitted by mosquitoes. Dr. Vincent told of the work of General Gorgas in eliminating yellow fever in Cuba and later in the Canal Zone, and, after his retirement from the Army, how he went to Central America as head of the International Health Board of the Rockefeller Foundation and established a League of Nations to eradicate the disease. The results of this pioneer and later work are that no yellow fever was reported from South America or Mexico during the past year.

"The conquering by science of animal grafting in the last few years has opened immense horizons," declared Dr. Serge Voronoff before a large audience of scientists gathered at the Sorbonne. "In fact," continued Dr. Voronoff, "man is now master of life. We cannot say that he is master of everlasting life, for as yet our experiments in rejuvenation are too new and the patients, although completely rejuvenated, have not had time to live long past the ordinary span of life. But there is every reason to believe they will. Why should there be a feeling of shame at undergoing a rejuvenation operation? Why combat the forward march of science?" The speaker then showed a startling collection of photographic slides portraying his various patients before and after their gland operations. One elderly Englishman appeared feeble to the point of senility; his eyes were faded, his face wrinkled with sagging muscles. Then a slide was flashed on the screen showing him one year after, with smooth, fresh face, flashing eyes—a young man once more. Next came the picture of a bitch, a dismal old creature, with her tail hanging dejectedly between her legs. The

next slide showed her one year later, sleek, gay and happy, and in the straw beside her six puppies.

THE OLYMPIC GAMES

Marquis de Polignac, as guest of the American Club of Paris at its weekly luncheon, gave one of the most interesting talks that has been heard by the club during the year on the timely subject of the Olympic Games. This pioneer in the revival of French sport, speaking from his long connection with the Olympic Games and as a member of the International Olympic Committee, gave high praise to the part played by America in reviving the ancient Greek custom of international athletic contests. The speaker's straightforward talk, which was in English, deeply impressed his audience. At the close of his address, it was announced that Marquis de Polignac had been elected a member of the American Club.

An aspect of the games which had not been widely appreciated up to the present was pointed out by the speaker when he called attention to the significance of the literary and artistic contests which will accompany the athletic sports at the coming Paris games.

"Following the ancient Greek custom," Marquis de Polignac said, "the arts, literature and music will be represented in addition to athletics at the international meeting in Paris. You remember that in ancient times, the greatest philosophers, litterateurs and sculptors gathered at the Olympic contests, and rivalled each other in showing their best work. It was on these occasions that the Greeks created the art which is now known all over the world. So in Paris, during May, June and July, there will be given at the Théâtre des Champs Élysées a special series of performances, including music, dancing, comedy and tragedy. Some of the greatest companies of the world, both French and foreign, will appear, while at the Grand Palais there will be an international exhibition of painting, sculpture, architecture and all forms of work inspired by the true ideal of sport. We have already received from many countries a large number of very good compositions in competition for the prizes of music and literature."

Marquis de Polignac, after reviewing the history of the Olympic Games, ancient and modern, assured Americans of a warm welcome from his countrymen, and he predicted a record breaking number of visitors from the United States to France this summer. He added that it was largely through American support that it was possible to revive the games at Athens in 1896.

"The Olympic idea," he said, "has always had a great success in the United States. The efforts which your countrymen are making in assembling and training a team to send to Paris is enormous. You will have 300 or 350 athletes here who will be almost unbeatable. According to figures I have been given at the Prefecture of Police there will be 350,000 American visitors to France during the summer and I am sure most of them will be here for the Olympic Games. I assure you that we in France very much appreciate Americans coming in such great numbers, and especially you taking such a wholehearted interest in the Olympic Games."

VIENNA LETTER

(From our own correspondent)

VIENNA, *June 2, 1924.*

EXAMINATION OF SCHOOL CHILDREN

Dr. Edmund Nobel, from the children's clinic of Professor Pirquet, has examined anthropometrically 1,836 children of school age confined in various institutions. He found the height in standing as well as sitting posture of the public school children greater than the height of the children living in institutions. The body weight of the institutional children is larger than that of other schoolchildren of the same age. In other words, while the growth in width is not disturbed the growth in length is disturbed. He concludes from his findings that institutional children should be fed more on food containing vitamine A, for instance, codliver oil.

AUSTRIAN RENAISSANCE

Just as the Austrian people at large, in spite of all losses suffered, are waking up to reassert their artistic talents, their idealism and love to create works of art—as evidenced by the various expositions for modern arts and crafts in the Austrian Museum, or the semiannual industrial exposition, called *Messe*—so the medical profession and men of science are beginning to show signs of a certain renaissance.

The anthropologicoethnographical collection situated in the state museum for natural history contains about eight thousand objects; it represents one of the richest collections of its kind in the world. The director of this department thought that it should be exploited scientifically and form a focus of research. Following the example set by Lundborg in Sweden, there will be arranged not only a modern craniological exposition but also an institution for racial biology. This new institution will pay special attention to research work in matters pertaining to the constitution and heredity of man as well as of domestic animals.

OCCULT PHENOMENA

The war has rendered the people's mind more prone to believe in mysticism; no wonder, then, that the study of the socalled occult phenomena has come into vogue. The German school of medicine as well as the Viennese school were always the most ardent disbelievers, while London had its society for psychic research many years ago and Paris, under the leadership of its most noted psychiatrists and neurologists, founded an institution for metapsychic phenomena in 1917. When Schrenck-Notzing, the psychiatrist of Munich, a few years ago created such a sensation by his book on occult phenomena, he gave a new impetus to the serious study of the subject. His photographic reproductions of the phenomena taken under all possible precautions, with the help of flash light, from six different places in the laboratory room, simultaneously and automatically, were quite convincing. He went even so far as to offer a standing price of twenty thousand francs to any trickster who would produce the same phenomena under the same conditions of control. The

offer has not been taken up by anybody as yet. And now Dr. Holub, a former pupil of the famous Professor Wagner von Jauregg (whose latest work is the cure of paralysis by means of intravenous injections with malaria tertiana blood), dares to announce, openly and convincingly the existence of similar phenomena. Dr. Holub, who since 1913 has been the physician in chief of Steinhof, an institution for curable as well as incurable mental diseases, with a capacity of three thousand beds, has had the courage to take into his home the famous medium, Willy Schneider, a boy, aged twenty, who is an unassuming and industrious dental technician. Since April 1923 he has had about sixty seances with the boy, inviting each time a few of the most prominent physicians, surgeons and scientists. These phenomena consist of medioplastic substance emanating from the body of the medium, who also moves distant objects not touched by anything or anybody in the room. Dr. Holub, in the face of the known attitude of the Viennese medical school, which had put its taboo on anything and everything occult, has openly declared himself converted from a Saul into a Paul, and while appreciating scepticism and just criticism in such matters, is seriously endeavoring to solve the new problems presented.

GASTRECTOMY

Another man, who has done work worth while, is Professor Finsterer, the surgeon, who performs gastrectomies under local anesthesia. In a paper delivered before the Medical Society of Vienna, early this summer, he stated that resection of the stomach shows no larger mortality than does simple gastroenterostomy; in a series of 236 resections for ulcer of the duodenum he had 3.4 per cent. mortality, which has been reduced—in the last 198 resections—to two per cent. He gets ninety-four per cent. good results, as compared with sixty-two per cent. cures or improvements after simple gastroenterostomy by Payr or thirty-seven per cent. by Haberer.

THE GOITRE PROBLEM

The goitre problem in Austria is a serious thing. About seventeen per cent. of the children between the ages of five to nine years, and twenty-nine per cent of the children from thirteen to eighteen are affected. The use of iodized table salt, which—as controls show—has produced good results. Wagner v. Jauregg has been making this claim in Vienna as far back as 1898 and finally succeeded in having the public health office of Austria decide upon the sale to the public of iodized table salt. This iodized table salt is now used in all State institutions—to the exclusion of any other table salt—and its use in all other State institutions, reformatories, orphanages, penitentiaries is recommended. To inform the whole population of Austria of the Government's intentions a million reprints of a popularly written pamphlet by Professor Wagner Jauregg on *Goitre and the New Table Salt* is broadly distributed.

RABIES

Dr. Schürer, in a paper read before the Medical Society in June, 1923, gave an interesting picture of the cases among the population of Vienna. Statistics show that 93.13 per cent. of human rabies are due to infection from dogs, 5.75 per cent. to that from cats. As preventive measures are recommended: compulsory wearing of dog tags, increase of taxes on dogs, compulsory muzling, preventive vaccination of dogs with Virus fixe.

ANGINA PECTORIS

Professor Eppingers has made the startling announcement, before the Congress for Internal Medicine, in April, 1923, relating to the cure of angina pectoris. This syndrome (paroxysms of retrosternal pain radiating along the ulnar nerve or into the shoulder or neck, coming on mostly after psychic or physical exertions, accompanied by a state of anxiety and pallor, but—in contradistinction from cardiac asthma—never causing dyspnea or heart alterations) has been considered by Eppinger an "Aortalgia in the sense of Rudolf Schmidt," in other words: due to a state of excitation in the sensory (sympathetic) branches within the aorta wall. The theory of Mackenzie did not seem acceptable to Eppinger, because the post mortem findings quite often showed no alteration in the coronary vessels. Inasmuch as the depressor nerves (according to Cyon and Ludwigs studies in 1866) is the "love and sensory nerve of the heart," conducting every irritation from the aorta, centripetally, the cutting of this nerve—according to Eppingers hypothesis—should stop the painful paroxysms. Working on this hypothesis Dr. Hofer operated on six patients from August, 1922, to April 4, 1923. He performs the operation first on one side—regarding as depressor only those branches which run freely into the chest cavity or after branching off from the superior laryngeal nerve or the vagus, again joining the latter—and, after the one side has healed completely and the larynx has been found intact he repeats the operation on the other side. One must, first of all, take care not to injure the vagus, because even the most insignificant squeezing may lead to paralysis of the vocal cords or to anesthesia of the larynx with fatal bronchopneumonia as a sequel. The effect of the operation in the remaining five cases was startling: the patients were freed entirely from their paroxysms.

ETHICS AND MORTALITY STATISTICS

The reawakened sense of ethics among the profession here takes a humorous turn at times! The Vienna Medical Society informs its members that it would be considered unethical and penalized accordingly if its members entered into any contract for having their names inserted in the city directory or in the appendix of the telephone book.

The general improvement in social economics is apparent everywhere, also in the statistics of births and deaths. In 1919 there were in Austria 110,822 living children born, in 1921 141,728—an increase from 17.96 per thousand inhabitants to 22.40. The number of deaths in 1919 was 125,449, in 1921 only 104,599, a decrease from 20.33 to 17.06 per thousand. How different are these same figures in Germany! About half of the number of babies born there are put into orphanages, in spite of the fact that the number of births has sunk to one third of its former rating.

LATIN AMERICA LETTER

(From our own correspondent)

CANAL ZONE, *June 4, 1924.*

ANIMAL LIFE IN PANAMA

The average visitor to the Isthmus of Panama sees relatively little of what is really going on. To him it is just a sort of superheated garden, which is very badly kept for the most part, and contains here and there a few ruins or picturesque bits of native life. He is herded about with a lot of tourists who apparently have just sufficient travel sense to go where they are shoved and whatever impressions he may take away with him are pretty apt to be blurred and incorrect.

What a pity! Here is a country which teems with historical interest—there is a wealth of botanical, zoological and ethnological material all about —there is an opportunity every few feet to study insect life—there are myriads of fish in the waters and snakes in every jungle—yet the average visitor and the average dweller of this region never see any of these things. At present, according to Mr. James Zetek, the entomologist of the United States Department of Agriculture on the Canal Zone, there are no less than one hundred and eighty distinct species and varieties of mammals in the Republic of Panama, many of which are extremely interesting. Some are very rare while others point to interesting happenings in the more recent geological history of this region. The fauna of Coiba Island, for example, is very distinct from that of the mainland. Some of the higher peaks in the Serrania de Tabarsara and similar country are today zoological islands harboring certain species not found elsewhere, or whose closest relatives now live in places quite distant.

More intensive scientific investigations are necessary, and when these are done, the number of species will no doubt be found to be about three hundred. There are represented in Panama three main climatic zones, the lower tropical, both humid and arid, the upper tropical and the temperate. Each has its distinct fauna, but the line of demarcation between them is not sharply drawn. There are species, for example, which live in both the lower and upper tropical zones but many of these are continued to the upper portion of the first and the lower portion of the second. The same thing occurs in the upper tropical and temperate zones.

Dr. E. A. Goldman, in his work on zoology, gives an historic sketch of those who have in the past studied the mammals of this region. The first was Lionel Wafer who did his work in the latter part of the seventeenth century; Thomas Bridges came in 1856 and the Dane, Orstea, in 1872; Enrique Arce, of Guatemala, collected for Salvin and Goldman, two Englishmen who did most valuable pioneer work on the biology of Central America and who edited the monumental *Biologia Centrali Americana,* which today is the backbone of our knowledge of the flora and fauna of the entire region. This huge masterpiece consists of sixty-five royal quarto volumes, citing and describing over eleven thousand plants and almost thirty-nine thousand species of animals. Of the latter, over nineteen thousand were new to science. The publication of this gigantic work began in 1879 and ended in 1915.

Real modern studies were not begun until March, 1900, when Wilmot W. Brown, Jr., launched his studies which were followed by such excellent collectors and students as Batty, Watson, Thomas Barbour, Osgood, Anthony, Shiras, Richardson and Goldman. In addition many of the employees of the Panama Canal, themselves amateur collectors, have sent mammals to museums in the United States.

Of the monkeys, the highest of our mammals, there are nine distinct kinds, belonging to six genera and six distinct families. There are the small titi, the night squirrel (marmosets), two kinds of howling monkeys, one of which is peculiar to Coiba Islands, two white throated capuchias, a red spider monkey and a black spider monkey, the latter being found only in the Darien country.

The insectivora, such as shrews and bats, are represented by only one shrew in the highlands of Panama and by at least forty-five different kinds of bats, representing thirty-six genera and six families. There are longnosed, white, bulldog, mastiff, flatnosed, longeared, smalleared, longlegged, fringelipped, spearnosed, vampire, false vampire, and many other different kinds of bats here.

The carnivora are represented by the various cats or socalled tigers, an otter, a skunk, a grison, a tayra, a weasel, two kinkajous, two Bassaricyons, a coati, two raccoons, a Bassariscus and a bushdog. The cats are represented by five species—the jaguar (often erroneously called a tiger), the ocelot or manigordo, the longtailed spotted cat, the puma (the socalled leon) and the yagouaroundi, the Panama gray and red cats. Some of these cats are very vicious and frequently numerous.

There are no less than seventy-four species and varieties of rodents in this area ,including thirty-seven genuine rats and mice, three pocket gophers, six pocket mice, five spiny rats, seven agontis and pacas (one of which is the Capibara, the largest rodent in the world), two porcupines, ten squirrels, including six pygmy squirrels, and four rabbits.

There are two species of tapir, three peccaries (wild pigs) and three kinds of deer. Two of the peccaries are the collared variety and the other is the whitelipped. Of the deer, two are whitetailed, one of which is peculiar to Coiba Island. The third species of deer is the common forest deer or brocket, known also as the cabra de monte.

Manatee are found in Chirqui Lagoon but none are known to exist on the Pacific side of the Isthmus.

The armadillos, anteaters and sloths form another big group, which includes two armadillos, the fourtoed and the fivetoed, three anteaters, the twotoed, the threetoed and the giant, and three sloths, two threetoed and one twotoed.

There are fourteen species and varieties of marsupials or opossums belonging to six genera in Panama. They are especially common around human habitations where they are harmless but rather more or less of a nuisance.

A movement is now on foot to create a zoological garden, at or near Old Panama, not only to exhibit the various mammals herein described but also collections of reptiles, birds, etc. This will not only be of great interest to the casual visitor to the Isthmus but to scientists who would enjoy seeing in this easy way such valuable zoological material.

Book Reviews

PSYCHOPATHOLOGY

Common Symptoms of an Unsound Mind. A Guide for General Practitioners. By G. Rutherford Jeffrey, M.D., F.R.C.P.E., F.R.S.E. With Foreword by Sir James Crichton Browne. New York: Paul B. Hoebler, Inc., 1923. Pp. 268.

The Recreating of the Individual. A Study of Psychological Types and Their Relation to Psychoanalysis. By Beatrice M. Hinkle, M.D. With Illustrations. New York: Harcourt, Brace and Company, 1924. Pp. 464.

The intentions of the author were no doubt of the best when he planned his work on the *Unsound Mind,* but just how useful it may be to the general practitioner, for whom it was designed, is somewhat dubious. It is not so much a question of the validity of Jeffrey's statements as one of their form. To the reviewer, it seems that too thin a slice had been cut from the cake to determine its quality. It is rather difficult to judge his somewhat novel way of handling the problem of psychopathology. The likelihood of its leaving the average reader in a state of bewilderment seems rather strong. This does not include the experienced psychopathologist, but to him the book would have little real value.

* * *

In spite of so excellent a champion as Doctor Hinkle, Jung's recent theories fail to convince the careful worker in psychopathology. The book is no doubt a conscientious piece of work and in spots contains many stimulating ideas, but on the whole it shows a rather impossible attempt to reduce behavior to a rather nebulous formula which is elastic to say the least. It seems as though Jung had taken a tiny fragment out of Pandora's box of human behavior and made a sort of Uneeda Biscuit formula out of it. The formula in this instance is subjective-objective intra-extravert. This is all very nice but what value it may have in getting at basic values seems highly problematical.

PSYCHOTHERAPIE

Psychotherapie. Charakterlehre, Psychoanalyse, Hypnose, Psychologik. Von Arthur Kronfeld, Dr. Med. et Phil. in Berlin. Berlin: Julius Springer, 1924. Pp. 260.

A remarkable on the fence piece of work to come this day from Germany. A scholastic effort to blend many halfbaked ideas into a fine pie. Just what useful function a work of this kind may serve is somewhat of a mystery.

PSYCHIATRY

Textbook of Psychiatry. By Prof. Eugen Bleuler, Director of the Psychiatry Clinic, Zürich. Authorized English Edition by A. A. Brill, Ph.B., M.D. New York: The Macmillan Company, 1924. Pp. xviii—635.

Bleuler's work comes with the authority of one rich in experience in direct contact with psychiatric problems and possessing a wide acquaintance with the work of others in the same field. Much more might have been said regarding compulsion neurosis which would have set it for the reader much further on the road of understanding and effectual treatment than the older descriptions made possible. Bleuler discusses it as if it still remained in this unillumined region. Here, as in other places, a fuller consideration of psychoanalytical experience would have furthered the subject. Bleuler accepts and uses psychoanalytical principles in part. The book is a worthy example of the modern spirit of investigation and progressive application of the interpretative point of view. Brill has rendered another distinctive service in bringing this work to the English reader.

PSYCHOANALYSIS

Psicoanalisis. Por Manuel Guevara Oropesa. Tesis que presenta para su examen general de medicina, cirugia y obstetricia. Mexico: Imprenta Victoria, S. A., 1923. Pp. 78.

Oropesa has written an interesting work concerning the place of psychoanalysis among modern methods of explaining and treating mental and nervous disorders. He discusses briefly the interpretations of the various schools. He reviews also in a general way the mental phenomena which are to be considered, consciousness and the subconscious, dissociation and the dream. He has a chapter also upon the neurosis and its close relation to the dream. He presents a more extensive chapter upon the practice of psychoanalysis. He reveals throughout the study an appreciation of psychoanalysis as a method of approach to mental problems, the importance of which cannot be overlooked, thus bearing strong testimony to its practical value. Yet he frankly avows dissent from its theories, at least as he views them, and he questions seriously the full scientific and therapeutic value which is attributed to psychoanalysis. Like most critics he seems to have missed the broader implications of certain points.

THE INSANE CRIMINAL

Insanity and the Criminal. By John C. Goodwin. New York: George H. Doran Company, 1924. Pp. 308.

This is a worthy heterodox view of the psychology of the criminal. The author has been catholic in his references, one might say to the point of a discriminating eclecticism. On the whole the book is interesting, well written, and presents the entire subject in a fluent yet highly intelligent way. More critical readers will no doubt regret that the author did not cultivate his ground more deeply, even though at the cost of a lessened acreage.

PROBLEMS IN MENTAL NURSING

Handbook for Mental Nurses. (Handbook for Attendants on the Insane). Seventh Edition, Seventy-Ninth Thousand. Published under the Authority of the Medico-Psychological Association. Chicago: Chicago Medical Book Company, 1923. Pp. xiii—615.

This book proves itself true to its former character as an authoritative presentation, simple yet comprehensive, of mental disease and the nurse's relation to it. It contains a brief general discussion of the nurse's personal requisites as to character and point of view toward the task. It presents a review of the various medical facts which form a background to this as to any other branch of nursing, bodily diseases and disorders to be met with, matters of diet and other measures which must be known to the nurse. The more obvious manifesta-

tions of consciousness are touched upon but special emphasis is given the unconscious activity as the basis of mental disturbances. Unquestioned testimony is given to the service which psychoanalytical investigation of unconscious content and mechanisms has rendered in the field of mental disorder.

THE NERVOUS SYSTEM

ANATOMY OF THE NERVOUS SYSTEM. From the viewpoint of the Development and Function. By Stephen W. Ransom, M.D., Ph.D. Second edition, revised. With 284 illustrations. Philadelphia and London: W. B. Saunders Company, 1923. Pp. 421.

In the second edition of Ransom's splendid textbook, which really includes a working laboratory manual, few changes have been made. The most important of these are the addition of certain clinical material which tends more clearly to portray the functional workings of certain nerve tracts. This is a commendable addition, and in line with the idea which has been so ably set forth in Tilney and Riley's classical work.

MOBILIZING THE MIDBRAIN

Mobilizing the Midbrain. The Technic for Utilizing Its Latent Power. By Frederick Pierce. New York: E. P. Dutton and Company, 1924. Pp. 259.

A book that has no scientific value, being a hodge podge of a little of this and a little of that. The book can do no harm, for anyone who could be influenced by material of this nature could get nothing out of the many worthy books on this subject which are procurable.

HOSPITAL ORGANIZATION AND MANAGEMENT

First Steps in Organizing a Hospital. By JOSEPH J. WEBER, M.A. New York: The MacMillan Company, 1924.

Hospital Organization and Operation. By FRANK E. CHAPMAN. New York: The MacMillan Company, 1924.

These two volumes are the first of a series of projected handbooks on various phases of hospital organization, construction and management, written by men of mature experience in the hospital field.

Mr. Weber is exceptionally equipped to prepare the volume which has appeared under his name. As editor of *The Modern Hospital* and formerly executive secretary of the Committee on Hospitals, State Charities Aid Association of New York, he has been in close touch with the problems of which he writes. In the preparation of his book the author has had in mind particularly the organization of the typical community hospital rather than the large institution in a metropolitan district. The introduction is devoted to a presentation of hospital statistics, their number in proportion to population, their distribution, and the like. In the following chapters Mr. Weber points out the great importance of careful planning by the community in the building of its hospitals. There must be a careful community study as to the number of beds that are needed, the type of institution that will be most useful, the location, as well as ways and means of maintaining the hospital once it is completed. He then discusses practical means which have stood the test of experience of enlisting community interest in the project, of authorizing and financing a preliminary survey, of procuring a charter and organizing a board of trustees. Finally the methods of financing the building operations are presented. The volume is a cheering commentary on the change that had come over hospital planning in recent years. Instead of a hospital being a vicarious outgrowth, born often of the whim of some wealthy benefactor, it is envisaged as a product of communal interest built and maintained by the community for the benefit of all its members. It is to be hoped that Mr. Weber's volume will find a large circle of readers among all those who are interested in organized community betterment.

* * *

Mr. Chapman, who is well known as a man who has contributed largely to the introduction of business methods in hospitals, is the author of the volume on *Hospital Organization and Operation.* Yet these efficiency methods are not an end in themselves. They are essential to enable the hospital to achieve, as Mr. Chapman says, its "ideal of service." In the compass of 265 pages every phase of institutional activities are discussed in broad outline. Chapters are devoted to principles of organization, administration, medical staff, nursing, dietary, social service, purchase and issuance, and similar topics. There is a liberal use of graphic charts and sample forms which will be found valuable. In spite of the comprehensive character of the book it abounds in practical detail, yet the author never loses sight of the broader aspects of the hospital problem. In his words "the hospital in its truest sense is an ideal of service, conceived and dedicated to combat disease, including within its operation all of the facilities known to humankind for the alleviation of suffering. Its operation is predicated upon a group of community problems and an inclination on its part to meet the demands of community service that may be made upon it."

Mr. Chapman's book should be in the hands of every hospital superintendent and trustee.

COMMON LAW

The Spirit of the Common Law. By ROSCOE POUND, Carter Professor of Jurisprudence in Harvard University, Dartmouth Alumni Lectureships on the Guernsey Center Moore Foundation, Season of 1921. Boston: Marshall Jones Company, 1923. Pp. 224.

This book contains an instructive survey of the history of common law as its theories and practices have been developed under the Anglo-American traditions. The debt of our common law to the older Germanic traditions, its contact with Roman law and the only slight influence received from this are touched upon in the presentation of the principles within which our law has had its existence. The fixed conceptions which have proved a hindrance in its past development and the gradual yielding of these to more flexible points of view are discussed with a broad openmindedness. This is evidence of the author's wide and deep knowledge of his subject and the quiet fearlessness with which he can look upon changes. These he welcomes as they bring our common law to a more concrete and a more adaptable service both to the individual and to the society in which he moves. Pound reveals how stubbornly in the legal profession the mind has clung to a conception of arbitrary law and of an abstract right for the individual. It is only slowly relin-

quishing these principles which it has sought by all the means of philosophy and history to establish. It is more nearly approaching that view which the writer unhesitatingly adopts, that law is the result of the working of many causes, something created by society in its own development and for the interests of the individual only in his relation to that society.

DIAGNOSIS

Aids to Medical Diagnosis. By Arthur Whiting, M.D. Senior Physician to the Prince of Wales's General Hospital. New York: William Wood and Company, 1924. Pp. viii, 1-177.

The author has succeeded in compressing within a small compact volume a great deal of what may be helpful in general medical diagnosis. The language is concise and clear, and the little book can serve not only the medical student as a condensed epitome of the larger textbook, but also as a vade mecum to the busy practitioner by refreshing his memory on salient points and prominent landmarks of disease. We note particularly that to the diagnosis of disease of the nervous system—the haziest and therefore the most difficult one for both students and practitioners to find their bearings—has been allotted the large space that its importance demands.

ROCKEFELLER INSTITUTE STUDIES

Studies from the Rockefeller Institute for Medical Research. Reprints. Volume XLVIII. New York: Rockefeller Institute for Medical Research, 1924.

These studies, consisting of almost six hundred pages, are the result of gathering together the reprints from the Rockefeller Institute for Medical Research, most of which appeared originally in the *Journal of Experimental Medicine* or the *Journal of Biological Chemistry,* and have already been abstracted in this journal. The subjects covered include pathology and bacteriology, biophysics, chemistry, experimental surgery, general physiology, animal pathology, and a few studies from the hospital of the Rockefeller Institute on diabetes, the lung volume in heart disease, and the question of sensitization of joints with nonhemolytic streptococci.

THE WORKS OF PARACELSUS

Theophrast von Hohenheim gen. Paracelsus Sämtliche Werke. Herausgegeben von Karl Sudhoff o.ö., Professor der Medizingeschichte an der Universität Leipzig und Wilhelm Matthiessen Dr. phil. zu München. I. Abteilung, Die medizinischen, naturwissenschaftlichen und naturphilosophischen Schriften. Sechster Band, Herausgegeben von Karl Sudhoff. Aus dem Jahre 1528 (Kolmar in Elsass) Mit Titelbild und 5 Tafeln. München: Otto Wilhelm Barth, 1922.

This first volume to appear under this extensive title gives promise of the valuable work which the editors have planned to put forth. They have chosen the sixth volume as the first to be issued since this and the volumes succeeding it in the series will contain the important works of the mature Hohenheim. Numerically preceding volumes will be devoted to the earlier writings and work of the famous physician and thinker. This volume is devoted to his discussion of wounds and open injuries and his extensive treatment of the subject of syphilis. The writings are faithfully reproduced in the author's own style, in authorship as in orthography. His style of writing is indeed a model in clearness and simplicity which scientific writers in his own tongue as well as in our own would do well to study and emulate. The complete edition of Paracelsus's works in this form, with the valuable discussions concerning the history of these writings and their first publication, will constitute a worthy addition to any medical or literary library. The reproduction of title pages, of original illustrations and manuscripts gives further testimony that the editors have entered upon their task with a true appreciation of its value from various cultural points of view.

COUNTRY PEOPLE

Country People. By Ruth Suckow. New York: Alfred A. Knopf, 1924.

Life, as truthfully reproduced as an album record. Commonplace, workaday life, and the incidents likely to occur in it. Miss Suckow's photographic ability has been noted by other reviewers. A few landscapes, family groups, local news clippings, comparable to the framed landscapes, family groups, and records of the parlors of just such country people as she describes. These make up her book.

But the connecting links between the vivid scenes are weak. There is narrative but little action. It seems incredible that in such lives as she describes there should be no drama even to the actors. What of the feelings of Emma Stille in youth, in marriage, in sorrow? In a chronicle of the minute details of their external lives, why so little of the inner world? One can guess more or less what is going on under the surface. But one cannot feel it. Some say that there are people who accept all and do not ponder over the ways of Fate. But what of the vast, empty spaces in such brains? Is there really nothing more poignant that the day's needs, and duties?

The book, we feel, with more of the human heart in it would be powerful. As it is it is interesting and good. Too good to be thrilling!

A MYSTERY STORY

Darkened Windows. By Cornelia Kane Rathbone. New York: D. Appleton & Co., 1924. Pp. 265.

A triple-decker mystery story that is closer to possibility than many we have read. However, it begins with the time honored convention of murder, against which convention one would like to inveigh. Not that the figures of crime are increased by the thousands of murder tales in circulation, but the fact that countless readers pant for the stories betrays a sadistic trend in the race that is not being improved by this particular brand of fantasy.

To return to our story: The bracelet plot, the murder plot, the radical plot, twist and weave into a chain of circumstance that holds attention for hours at a stretch. And there is the amateur detective who in the long run does unravel the mystery. Who committed the murder, what happened to the misplaced bracelet and what have all these elements to do with the nationwide radical plot? Nothing—and everything. Each is a thing by itself, and yet by the freaks of association they are inextricably blended.

There may not be the punch of the professional mystery story in this book, but there is undoubtedly good material, original theme, and straightforward handling.

Medicoliterary Notes.

In a recent address, Dr. Edwin L. Ash, of London, specialist in nervous diseases, stated that some of the fogs experienced by London during last winter were real varieties of mustard gas. They contained all the acid and irritating ingredients of poison gas and affected the delicate membranes of the throat and respiratory organs. Many children contracted actual fog poisoning.

* * * *

Montmartre in Paris has a café in which a sign hung in a conspicuous place last winter reading as follows: All conversation about the grippe is strictly forbidden.

* * * *

A comprehensive survey recently made by the Eyesight Conservation Council of America has revealed that more than sixty per cent. of the elementary and secondary school children in the United States have eye defects that warrant correction. Six million children, or twenty-five per cent. of the total public school population, are suffering from impaired vision to such an extent as to handicap them seriously in getting an education. The Eyesight Conservation Council, organized three years ago for the purpose of conducting a national campaign to arouse public interest in the problem of eye hygiene, has three main objects in view: 1, To correct defective vision; 2, to procure nation-wide eye protection against injury; 3, to insure adequate provision for proper illumination.

* * * *

Dr. Gustav Gaertner, a German professor, has conceived the idea that the early hours of the morning might well be devoted to radio broadcasting for the blind exclusively. A single speaker could thus reach the blind and those with defective vision throughout a very large area. He suggests finding out what such persons would like to hear through a round robin addressed to the blind themselves. He himself suggests a program of important political and current events, followed by an hour of reading from good literature, both fiction and more serious works, and possibly a third hour of simple scientific information.

A new device has recently been developed by the U. S. Bureau of Standards whereby the electrical conductivity of sea water may be measured and indicated in terms of its saltiness. This new application of electricity to the safety of those at sea is expected to be of great value in giving warning of the proximity of icebergs, since these often greatly dilute the saltiness of the water in their vicinity.

A brilliant young Hungarian biologist, Theodor Koppanyi, after a long series of investigations and experiments, has succeeded in successfully grafting new eyes on animals, including not only the lower forms such as frogs and fishes, but also rats and rabbits. The scientist reports that not only did the eyes accommodate themselves to their new quarters by physiological growth, but that the animal recovered vision after the wound healed.

Einstein conceives of all education as a free and living process, with no drilling of the memory and no examinations, but mainly a process of appeal to the senses in order to draw out delicate reactions.—*Havelock Ellis in The Dance of Life.*

* * * *

Richard Strauss seems to have attained the very pinnacle of that realistic musical interpretation in which he indulges so freely and successfully in his *Whipped Cream Ballet* recently performed in Vienna. The plot is based on the old and too familiar story of the boy who has eaten too much, and as a consequence has a nightmare. The German critics have declared the music to be delightful and that the first audiences were enraptured.

Lecturing at the Royal College of Surgeons, Sir Arthur Keith, the distinguished English anthropologist, has declared that the face of modern man is growing downward and that corresponding changes are taking place in the upper bones of the face. Only part of the Western race—from twenty to thirty per cent.—is affected. . . . Sir Arthur does not attempt to account for all this. It does not even seem to occur to him that postwar conditions give most people in the modern world pretty good reason for long faces, or that, as an unscientific contemporary suggests, the modern jaw is dropping in sheer astonishment at modern science.—*Living Age.*

Psychic Messages from Oscar Wilde, edited by Hester Travers Smith, and published in London by Werner Laurie, is a curious but most interesting production. However unconvincing it may be, the book has one great difference and merit over other socalled spiritual revelations in that the ghost who talks in this one has real intelligence, and does not have to resort to cold chills down the spine, jingling tambourines, and skeleton hands to make himself known. What he says is not only intelligent but often extremely clever and interesting.

Dr. Edwin G. Ramsdell, health officer, has just reported that the infant mortality rate of White Plains, N. Y., during 1923 was only 38 in 1,000 living births, which is believed to be the lowest ever attained by any city of the State. It is less by half than the infant death rate for the whole State in 1922.—*New York Medical Week.*

The *Missouri Botanical Garden Bulletin* tells us that meal made from the acorns of the various kinds of white oaks is very nutritious and digestible. It was formerly one of the chief foods of the Indians of North America.

* * * *

A recent publication of Putnam's is *Eyeless Sight* by Jules Romain, a French physician and litterateur who has been investigating extra-retinal vision. His theory is, says the *New York Times,* that in the dim past man, like many of the inferior animals, was endowed with the ability of seeing through his skin, an ability that has been lost through disuse. He believes that there exist all over the body tiny "ocelles" or undeveloped eyes, and that these may be developed so that they will again be able to see. Experiments are being carried on in France, particularly among blinded victims of the war, and it is said that some remarkable results have been obtained, some of the subjects being able to distinguish colors and even figures without the use of their eyes.

The *News Bulletin* of the Public Service Information Committee of Philadelphia tells us that electrical experts have been able to estimate that a brilliant flash of lightning is worth about a dollar.

* * * *

The great stone woman found not long ago in the most remote forests of Oregon near Crater Lake has been explained. She is the work of an amateur sculptor and physician, Dr. Earl R. Bush, of Cincinnati. Seven years ago he came with a party of engineers into the great forest, the spirit of which permeated him with its sense of mystery, silence and vastness, until he became possessed with a desire to express it in some way. He asked the blacksmith of the party to lend him his chisels and worked for days until the great figure was hewn from the solid rock. Soon afterward the party returned to civilization and the statue was left alone in the forest, where it remained apparently undiscovered until another party of engineers happened upon it a few months ago.

In speaking of the emancipation of women in India in a recent address, Miss Jane Addams told of the many who were taking advantage of the free medical courses for women. She mentioned one maternity hospital at which the prospective mother was permitted to bring her entire family during her confinement. An apartment for the family was set aside and even the mother in law was included in the family circle.

Abstracts from Current Literature

NEUROPSYCHIATRY

Tantrums in Childhood and Related Emotional Reactions.—Edith R. Spaulding (*Archives of Pediatrics,* March, 1924) states that while tantrums are not to be encouraged as constructive outlets of energy in the development of a personality, they may be looked upon, when they occur, as valuable signals of the needs of the individual in the socialization of his egotism. They are closely related to the physical and mental conditions of later life that represent efforts to escape from disagreeable phases of reality. In this respect they may be considered precursors of mental disease and of abnormalities of character formation. Among the important underlying factors of tantrums may be found a thwarting of desire, a resistance to authority, chagrin at the failure of some compensating mechanism, feelings of inferiority and inadequacy either real or imagined, and flight from unpleasant situations. The treatment of tantrums should be based on a study of the individual child. He should be helped to express his energy in an adult rather than in childish ways and to make assets of what have hitherto appeared as liabilities. He must be shown that the way to power and to normal health lies through the difficulty rather than around it. The recognition of the importance of such emotional explosions in childhood and their subsequent treatment should be of material help in the prevention of mental and nervous conditions later in life.

Factors Favoring Epileptic Seizures.—P. Hartenberg (*Presse médicale,* April 30, 1924) states that certain favoring factors play a much more important rôle in the pathogenesis of epilepsy than is generally thought; often no seizures would occur without their participation. The most obvious contributory factor is sleep, seizures often occurring either shortly after falling asleep or in the period between 3 and 5 a. m. Some cases, again, have seizures only after awakening; the seizures occur at whatever time they awaken and even if they stay in bed after the awakening. Some women have seizures only near the time of the menses. Often in girls the seizures begin at puberty. The menopause may induce initial seizures or cause them to return after prolonged recovery. Pregnancy improves one half the cases but makes one fourth of them worse. Coitus and masturbation have been reported to be factors. Ingestion of food is a well known exciting factor, seizures coming on either soon after the beginning of a meal or later. In some subjects, distention of the stomach by a large meal or by too much fluid—especially carbonated fluids—exerts a definite harmful influence. The same is true of rapid eating and insufficient mastication. Among the special foods the author has found apt to bring on seizures are fat broth, eggs, sugar, pastry, and cooked fats; the seizures diminish when these articles are withdrawn. Indigestible foods, such as cabbage and cucumber, and fermentable articles, such as starches and legumins, also promote seizures. Placing a series of patients alternately on a meat diet and a stringent low nitrogen diet, the author found, contrary to a prevalent belief, that the latter diet caused no improvement, but at times even aggravation. Blood examinations led to the conclusion that the food proteins generally are not a factor in the pathogenesis of epilepsy. Other factors referred to are active congestion of the head, as by staying in a warm, confined atmosphere; passive congestion of the head, as upon exertion or stooping; cerebral anemia, as by compression of the carotids or rising from bed for the first time after typhoid fever; emotions; vagotonia; exposure to cold; a hot bath; cold showers; fatigue; insufficient sleep; insufficient food; rapid growth in adolescents; varying seasonal influences; barometric changes; digestive disorders, especially putrefactive conditions and rapid evacuation, but also sometimes gastric insufficiency and parasites; intermittent diarrhea, the seizures returning when the diarrhea sets in; toxic foods and beverages; various drugs, such as opium, ether, cocaine, ergotin, nicotine, quinine, calcium, amyl nitrite, nitroglycerin, atropine, pilocarpine, eserine, purgatives and laxatives; enemas, endocrine disturbances; fevers (either beneficial or harmful); diseases such as diabetes, obesity and anemia; chronic suppurations in the nasopharynx or the reproductive organs in women, and high or low pressure of the cerebrospinal fluid. These various factors have no specific pathogenetic significance, but are well worthy of thorough investigation in the different cases. In one young woman in whom attacks were brought on by heavy meals with carbonated waters, a reduced diet removed the seizures, though bromides had failed. In a case in which series of seizures were always preceded for two or three days by diarrhea, a suitable diet likewise proved completely effective. In another case, cessation of masturbation was followed by cessation of seizures. In one patient the disorder was checked by correction of chronic enteritis, insufficient sleep and repeated special emotions. In another instance the same result followed treatment of five factors, viz., ovarian insufficiency, dilatation of the stomach, constipation, congestion of the head and obesity. Such a suppression of the favoring factors is especially effective in the early stages of the disease. The initial attacks often appear in a quite accidental manner, being distinctly the result of such factors. Later the epileptic habit becomes established and such satisfactory effects are much harder to obtain.

Weakness in Ulnar and Median Nerve Lesions.—L. J. Pollock (*Surgery, Gynecology and Obstetrics,* March, 1924), comments as follows upon his series of illustrated cases:

ULNAR NERVE LESIONS.

Physiological interruption cannot be differentiated from anatomical section by the strength of movements of the phalanges of the fingers. In recovering and partial lesions, relatively greater strength in the phalanges is observed but may at times be an inaccurate guide to the severity of the lesion. Relatively greater strength in the first dorsal interosseus, or in the abductor of the little finger, is an accurate guide as to the incompleteness of a lesion. Of course, any movement of the flexor carpi ulnaris or adductor of the thumb which is not supplementary in character determines an incomplete lesion. Sensation was completely lost in all severe partial lesions. Where sensory regeneration had occurred, usually motor recovery could likewise be demonstrated.

MEDIAN NERVE LESIONS.

Physiological interruption cannot be differentiated from anatomical section by the strength of the movements of the phalanges of the fingers. Although in a considerable number of cases the movements of the index finger were stronger, this could not alone determine the character of the lesion. Return of function in the opponens pollicis would indicate a partial or recovering lesion but because of supplementary motility is very difficult to determine. The author calls attention to a supplementary movement producing abduction of the thumb at right angles to the palm which he had not before noted. When the metacarpophalangeal joint of the thumb is partially ankylosed, so that no flexion or extension in the plane of the palm is possible, contraction of the extensor longus pollicis and the extensor ossis metacarpi pollicis produces abduction of the thumb as above described.

Sensory regeneration or incomplete sensory loss in the area supplied by the median nerve is almost constant in complete lesions and in otherwise physiologically complete ones; i. e., sufficiency serve partial lesions to come to operation. In a large proportion of partial or recovering lesions sensory regeneration is present when motor phenomena give no indication of regeneration.

ULNAR AND MEDIAN LESIONS.

When observed sometime after injury it would appear that anatomical section of both ulnar and median nerves produces complete paralysis of all the phalanges of the fingers and thumb; and severe lesions, not anatomical sections, show some movement in some of the phalanges of all of the fingers. In incomplete lesions of either ulnar or median nerves, weak movements of the phalanges of the fingers, if interpreted alone, are insufficient guides as to whether one of these nerves is severed and as to which one may be severed. As in isolated lesions of the median nerve, so when combined with an ulnar nerve lesion it was seen that in partial or recovering lesions and in more

than half of the severe lesions, not anatomical sections, incomplete sensory loss in the median distribution was present. In complete lesions of the ulnar and incomplete of the median when sensory regeneration was demonstrable, motor regeneration was likewise present.

It is emphasized that recovering or incomplete lesions of the median nerve may almost regularly be determined by sensory examination, whereas in ulnar lesions this rule does not apply, contrary to the generally accepted statement that signs of sensory regeneration are first to appear.

SYMPOSIUM ON PAIN

(*Surgery, Gynecology and Obstetrics,* February, 1924)

The Surgical Significance of Pain.—W. D. Haggard regards pain as a defense mechanism against injury whose chief outpost is the cerebrospinal system, a later addition to the nervous system. The vegetative nervous system which has to do with the primitive processes presides over these essential functions and at times conveys pain in an exaggerated way during the normal events of digestion and elimination. If harmful afferent stimuli pass to the cord over a long period of time, the threshold of response of the nerve cells which receive these stimuli is necessarily lowered and they respond to a stimulus which is much below that which they would ordinarily withstand. Hyperirritability of these cells permits a lesser stimulus than normal to produce a heightened response.

While diagnosis by pain is now remarkably well developed, especially in regard to abdominal pain, he points out that though pain is a striking symptom requiring interpretation, it is the collateral symptoms that clinch the diagnosis. He discusses briefly the pain of gallstones, and of acute perforation of the stomach, abdominal pain in children with beginning pneumonia and its similarity to appendicitis, etc., and then considers the subject of pain from the neurological viewpoint, stating that only by knowledge of the nervous distribution can one correctly interpret the occult origin of pain, for it is the relative significance of pain that must be taken into account. He says: "We have learned to be so suspicious of the pain complained of by the neurotic that occasionally their cry of 'wolf' is unheeded. Their pain may depend upon an abnormal personality rather than an organic abnormality. They need a physician who can 'raze out the written trouble of the soul.'"

Pain with Surgical Lesions of the Eye.—J. M. Patton discusses glaucoma, pain of the blind eye, iritis, corneal infections, etc., summarizing his findings as follows:

Let us remember that a severe neuralgic headache with or without nausea should suggest the possibility of acute glaucoma; that the pain of iritis is worse in the second half of the night; that sudden pain in one eye during the course of a general septic process may mean a destructive panophthalmitis; that pain in or about an old blind eye is an intraocular sarcoma unless proved otherwise; and that even though the pains indicating the lesser lesions mentioned may not indicate such grave conditions, they are worthy of recognition by the general surgeon and his prompt intelligent advice will entitle him to the heartfelt gratitude of his patient.

Intracranial Pain.—J. F. Barnhill describes pain, particularly intracranial pain, as follows:

Pain anywhere probably is always caused by absorption of toxic products by sensory nerves, or by their traumatism. This pain may be due to pressure, to infection, or to pressure plus infection. Environment has much to do with the ease with which pressure pain is produced. In regions where loose tissues prevail, as in the neck, the pressure of a growing tumor, or of an exudate, pushes the sensitive nerves aside, and pain is delayed. Inside the cranium conditions are different. No structure within the skull may be pushed aside without causing definite traumatism and positive pain. The dura mater, because of its position next the skull, is the part most easily traumatized by intracranial pressure. It is also the only intracranial tissue that is to any degree endowed with sensation. The pia mater has but few sensory nerves, while the arachnoid is wholly insensitive. In the dura mater, therefore, all intracranial pain originates. The actual cause of the pain often lies in the deeper structures of the brain, but the influence of that cause must in some way reach the dura mater before pain may be produced. Intracanial pain, it would seem, is always in the end an affection of the dura mater. The dura is the sensory organ of the brain.

He goes on to say that the physiological status of the brain is disturbed chiefly by the entrance from without of infection or the products of infection. The healthy brain is menaced by the invasion of infection from two sources, namely, through the blood stream, and by direct entrance through the skull itself.

Intracranial pain, therefore, is due usually to a definite assignable cause, and may often be traced to some external, clearly understandable source. The paranasal sinuses and the mastoid cellular labyrinth are the commonest foci of origin. Or, the intercommunicating blood stream may carry the infection from the septic cell to the sterile brain. The result is the same in either case. Inflammation is set up, inflammatory products are formed, intracranial pressure is increased, the sensitive dura mater is crushed against the skull, and intolerable pain is produced.

In tic douloureux he states that the external pain is but a reflex. Both the disease and its terrifying pain are in reality inside the skull.

A second type of intracranial pain is due to the circulation in the brain of toxic substance within the blood. To this type belong the headaches of indigestion, of constipation, migraine, the headaches heralding meningitis, typhoid fever, measles, etc., also Bright's disease and glycosuria.

In tumors the severity of the pain may be out of proportion to the size of the tumor. Its location may have much to do with the amount of suffering.

He concludes: Intracranial pain is undoubtedly less frequent today than formerly. It has to no inconsiderable extent been prevented or conquered by modern medical and surgical science. The internist and laboratory expert, working together, have discovered the cause and nature of blood stream infections acting on the brain to cause pain, and have in several pain producing diseases, notably in syphilis and diabetes, robbed these diseases of their most terrorizing symptoms. Surgery also has added greatly to the relief of intracranial pain when due to tumor growths or fluid collections.

Pain in the Ear.—F. M. Sulzman stresses the importance of knowing whether the pain is due to a lesion about the ear or is a reflex pain due to a lesion in some other part of the body causing this phenomenon. Nearly all pain about the ear proper is from pressure. Diagnose early and locate the cause of pain in the ear; relieve the pressure, institute adequate drainage, and in the majority of acute ear cases, in which pain is complained of, recovery is prompt.

Several factors enter into the degree of pain experienced. First, the patient, who may be one of two types, the oversensitive or the hyposensitive, which latter do not come for treatment until their ailment is in the late stages. Second, the type of infection; in cases with marked destruction of tissue from a streptococcus capsulatus infection the pain may be mild or altogether absent; the same holds true with many of the tuberculous type. Third, the character of the bone dealt with. The pneumatic and ebony type will each have special symptoms. In the soft pneumatic bone pain on pressure will be great, but the patient will complain very little, as pus has found an easy passage toward the cortex. In the ebony type the patient complains of much pain and pressure will not reveal it even until later in the course of the disease.

A case presenting headache and vomiting with a history of previous ear discharge with or without pain directly in the ear, should warn of a likely intracranial complication, meningitis especially. Pain is one of the early symptoms of brain abscess and it should be remembered that the site of pain is no guide to the location of the abscess, occipital pain being present in many cases of temporosphenoidal abscess, while frontal pain is found in cerebellar involvement. Aphasia, if present, would aid in locating the abscess in the left side. In all these infections associated with deafness, vertigo, nausea, and nystagmus, examine the labyrinth for the source of the trouble.

Pain in the Joints and Back.—R. D. Kennedy describes the pain of the various diseases of the joints and back, dividing these diseases into several groups, namely, those due to injury; those due to arthritis; those due to traumatic neurosis; those due to new growths; those due to uterine, pelvic, or abdominal disorders; those due to postural or mechanical strain; and those due to a myositis of the muscles of the back.

He recommends the x ray as the only possible means of diagnosing minor fractures. In cases of sprains where

compensation is involved he points out the difficulty of treatment owing to the delayed settlement, and locates the pain due to adhesions in the region of the seventh cervical or dorsolumbar junction, and over the fifth lumbar vertebra and sacrum. In cases of altitudinal strain the x ray shows no displacement.

Pain and Gynecological Affections.—R. R. Smith emphasizes the fact that gynecological affections seldom give rise to backache. When they do, the pain is more likely to be in the sacrum than in the lumbar region. The cause of the common lumbar backache of women is to be sought in fatigue, in faulty posture, and occasionally in arthritis, and not in the pelvis. Headaches of all description and pain in remote parts of the body are not caused by gynecological affections. Such remote pains and backaches are frequently associated with pelvic difficulties, but not caused by them, and it is imprudent to promise their relief by surgical or other gynecological measures. The old time socalled reflex pains are a matter of historical interest only.

He discusses the pain symptoms of the various gynecological diseases and, lastly, takes up the question of neurotic pain with respect to the sex organs as follows:

"Often, we find pain, when so far as we are able to determine, the organs are normal or present lesions that should not be painful. The pain, so far as the location goes, simulates very closely that attending real lesions of painful nature. There is nothing that requires greater diagnostic skill on the part of the gynecologist than the accurate estimating of the physical condition of the pelvic organs and the part that the nervous system is taking in the symptomatology.

"The term neurosis is almost as general as the term disease, so varied are its manifestations. We must bear in mind first that we are dealing with sensitive functionating organs and not inert ones. Our conception of what constitutes a neurosis may vary greatly; gynecologists are not neurologists nor are most of them profound in their knowledge of neurological literature, but in a general way it may be said that two principal factors enter into the production of pain in the nervous neurotic woman. The first is an oversensitiveness of the patient, so that organs ordinarily functionating painlessly now do so painfully. The second factor lies in the mind of the individual, whose faulty conceptions as to the integrity of her sex organs and the attending anxiety in regard to them exaggerate normal sensations into those of pain or discomfort. There are almost always other manifestations of the neurotic condition. We are dealing then with a functional disturbance of the nervous system, of which pain in the pelvic region is but a symptom. The success of the gynecologist in his particular field of endeavor will depend largely upon a rational understanding of such situations and his determination to refrain from instituting surgical measures."

Pain and the Genitourinary Tract.—A. J. Crowell describes in particular the pains of kidney diseases. Of kidney pain in general he holds that it is due to some stimulation of the sensory nerve supply of the kidney. Severe kidney pain is the result of some acute process and is divided into the inflammatory and noninflammatory types. The inflammatory type is constant, aching in character, increased by palpation and percussion while the non-inflammatory type is more sudden in onset, more severe and paroxysmal in character and disappears more suddenly than that due to inflammation. The patient lies on the opposite side to prevent pain in inflammatory conditions and on the affected side when pain is due to kinked ureter in nephorptosis, or any non-inflammatory condition causing sudden ureteral occulsion. Inflammatory kidney pain is increased more by deep breathing than by motion. That caused by kidney congestion is better in the morning and worse in the evening. The latter is not eased by fixation and is sensitive to deep pressure.

Human Vegetative Functions.—W. J. Mayo (*Surgery, Gynecology and Obstetrics*, March, 1924), says: "The era of surgery based on gross pathology is passing. Investigations of a physiological nature are enabling the detection of pathological changes in tissues in the early transitional periods; this fact leads to the hope that many diseases can be recognized at such an early stage of deviation from the normal that they may be prevented from assuming serious aspects. Cathcart and Benedict estimate that only twenty-five per cent of the energy produced in the body can be expended by the tissues under the control of the will, seventy-five per cent being used by the vegetative functions of the body, of which we are unconscious. In order to obtain a general view of the subject I have reviewed briefly, as related to those functions of which we are conscious (twenty-five per cent), some facts and near facts which underlie the mechanism of coordination and control of the vegetative functions (seventy-five per cent)."

Prefacing a brief and stimulating treatise with these remarks the author elaborates upon the following headings in turn; nonstriated muscle; the eight neuromuscular nodes; the internal secretions; the autonomic nervous system; and the central nervous system and the vegetative functions. He concludes with the query: "Are not many, perhaps most, of these unstable nervous conditions, socalled neuroses, which are exploited by the cults and quackeries, the results of an attempt of the newer part of the nervous system to take control of previously established coordinating functions, unrighteous attempts at control of the sympathetic ganglions, the internal secretions, and the primitive nonstriated muscle by an unbalanced recent development of the forebrain?"

Early Mechanical Treatment of Acute Anterior Poliomyelitis.—Harry Platt (*British Medical Journal*, February 16, 1924), advances the following fundamental surgical principles: 1. Complete rest through the use of a molded plaster of Paris bed or a well padded spinal frame of the double Thomas or Bradford type, with the addition of suitable splints for the limbs; 2. the prevention of deformity by the adoption, from the moment immobilization is affected, of certain standardized positions of the limbs—positions which are known to be antagonistic to the occurrence of the common contractures. The correct position for the lower limb is extension of the hips and knees, with the feet maintained at right angles to prevent the classical triple deformity of flexed hip, flexed knee and foot drop. For the upper limbs the positions are: right angle abduction of the shoulder, flexion at the elbow with supination of the forearm, and, where necessary, dorsiflexion of the wrist. 3. Relaxation of the paralyzed muscles is necessary. When the stage of recovery sets in and the paralysis becomes much more localized, the principle of physiological relaxation may be applied with a greater degree of accuracy. Once the patient is comfortably installed in his shell or frame, he should be subjected to the minimum amount of disturbance during the following weeks. In the average case the child will be brought into the sitting posture by degrees some time after the fourth to the sixth week. Surgical treatment should not be begun until the diagnosis is completed.

Pneumoventricle of the Cerebrum.—F. R. Teachenor (*Annals of Surgery*, November, 1923), reports on an unusual case which he compares with other classical cases from the viewpoint of the course of the air route, and of which he says:

The author wishes to offer a probable route more applicable to his case, which is the only reported case in which the fracture was through the external auditory meatus and the petrous portion of the temporal bone. As the cerebrospinal fluid escaped from the right ear it is assumed that the air gained entrance by the same route. Fractures in this region tend to cross the floor of the middle cranial fossa to the floor of the sella turcica. The floor of the third ventricle lies in this region. The floor of the third ventricle in the postchiasmal region and about the tuber cinereum is very thin, and the infundibular process of the third ventricle passes well into the pituitary stalk. A fracture in this region, with a sudden displacement of the brain placing these tissues under tension, might easily lacerate into the third ventricle, and permit an egress of ventricular fluid and an ingress of air. The air would then readily pass through the foramina of Munro into the lateral ventricles. This route has not been established, but is offered as a plausible and probable route.

As the presence of air in the cranial cavity or ventricle does not in itself cause any deleterious effects, the treatment should be directed against its most common complications: 1, Meningitis; 2, intracranial compression, and 3, its tendency in intracranial aerocele to the formation of cysts by replacement of the absorbed air with fluid.

Aseptic and antiseptic treatment of the wound of entrance of the air is of prime importance. Air in the ventricles is rapidly absorbed, and in the absence of other

indication for operative measures, notably increase of intracranial pressure, may be ignored. In the cases of intracrinial aerocele the air seems to be absorbed more slowly, and on account of its tendency toward cyst formation, should be aspirated or drained. Drainage would also tend to lessen the danger of meningitis. The drainage or aspiration, if done, should be done early. The accompanying skull fracture and brain injury will usually indicate the type of treatment to be employed. Pneumoventricle of the cerebrum probably occurs more frequently than the literature indicates.

Specific and Nonspecific Treatment of General Paralysis.—Franck (*Schweizerische medizinische Wochenschrift,* February 14, 1924) confirms the theory of Wagner that a hematoencephalic barrier, which prevents the passage of drugs from the blood into the brain, is weakened by acute infectious diseases, but that it is made more impermeable by arsenical, alcoholic, or morphine intoxication. The species of spirochete invading the central nervous system also favors an increased resistance against the therapeutic agents. After nonspecific treatment that induces fever the attack on the spirochetes is facilitated.

Anesthesia of the Splanchnic Nerve.—H. Fischer (*Annals of Surgery,* March, 1924) states that the vagi have nothing to do with the sensibility of the abdominal organs. The anesthetization of the abdominal organs can therefore only be accomplished by blocking of the splanchnics and the lumbar sympathetic trunk. He recommends Kappis's technic of anesthesia of the splanchnic nerve. He reports on various cases in which he has used this method, and comments as follows: It is undoubtedly a satisfactory method of anesthesia in severe surgical conditions of the upper abdomen where we feel that a general anesthesia would be better avoided. Personally I have not observed any ill effects from this mode of local anesthesia and do not hesitate to recommend it in suitable cases. The technic is not any more difficult than that of a spinal anesthesia.

Treatment of Infantile Paralysis.—A. T. Legg (*Journal of Bone and Joint Surgery,* January, 1924) emphasizes in his conclusion the following points: The evil results of overfatigue, general exercise treatment without regard for muscle balance, weight bearing without mechanical support in positions which favor deformity, tendon transplants without regard for the bony mechanics of a foot, are not matters of theory, but are facts which have been proved by the personal examination of twenty-four hundred cases, not only once, but many times.

Late Ulnar Nerve Palsy.—E. M. Miller (*Surgery, Gynecology and Obstetrics,* January, 1924) concludes from his study that fractures of the external condyle of the humerus, which occur most often in childhood, should be operated on if the loose fragment cannot be accurately reduced by manipulation, because the growth disturbance following nonunion is likely to result in a marked valgus deformity which may in later years produce a paralysis of the ulnar nerve. If this occurs, it is the duty of the surgeon to relieve the tension on the ulnar nerve as soon as the first signs of paralysis appear, either by a correction of the deformity, as recommended by Mouchet, or by transplantation of the nerve to the flexor surface of the elbow.

Compensation Neurosis.—George E. Price (*Northwest Medicine,* April, 1924) discusses a number of cases and arrives at the following conclusions:

Compensation neurosis is a definite and frequent clinical entity which may develop shortly after the initial accident, injury, wound or war experience, or may be delayed for a considerable time.

The neurosis may occur in association with an actual physical injury or may appear as an independent condition.

Three distinct factors contribute to the etiology of a compensation neurosis: first, the underlying neuropathic predisposition; second, the intermediate or pivotal element —the accident, injury, wound, or war; third, suggestion as to compensatory possibilities.

It is more difficult to tell where hysteria ends and malingering begins than to differentiate between hysteria and an organic disability.

In an accident case, prompt settlement of the claim by the party liable constitutes the best treatment (preventive).

When an individual afflicted with compensation neurosis is receiving a pension because of such disability, the continuation of the pension is bad for both the individual and for society.

Brain Abscess with Pathological Observations.—C. Bagley (*Surgery, Gynecology and Obstetrics,* January 1924) finds from his study of twenty brain abscesses that there are four avenues of infection, namely:

Group I. Presence of an extradural extension of the primary focus, with protrusion of the distended dura into the cranial cavity, direct extension from the extradural abscess, or invasion from the extradural abscess along the bloodvessels.

Group II. Secondary invasion of the brain along the bloodvessels without extradural link.

Group III. Penetrating brain injury with infection by foreign body, deep, with or without stalk: Path infected and open, hence long abscess stalk; path healed, hence no abscess stalk.

Group IV. Abscess superficial and open, secondary to direct laceration and infection of brain tissue.

As regards the behavior of the brain with regard to the formation of the abscess wall after the introduction of infection, he concludes that the clinical course of a brain abscess varies according to the infecting organism, the channel through which this organism reaches the brain, and the location of the infection in the brain substance as regards mesoblastic and epiblastic tissue.

This pathological study has been made as a basis for further consideration of the clinical data concerning these abscess cases.

Treatment of Congenital Cerebral Herniæ.—F. M. Lampert (*Surgery Gynecology and Obstetrics,* February, 1924), presents the following conclusions to his study:

1. Encephalocele is a dystrophy of the medullary tube occurring early in embryonic life. It is associated with protrusion of the meninges, brought on by disturbances of lymph and blood circulation and the consequent increased intracranial pressure.

2. Meningocele does not exist as a special morbid condition.

3. The cause of the dystrophies of the medullary tube lies in numerous embryological factors, such as processus neuroporicus, neuroporus anterior and posterior, occipital curvature, canalis craniopharyngeus and others, in association with traumatic influences during intrauterine life.

4. Conservative treatment of encephalocele does not give favorable results.

5. If operation is indicated it should be performed within the first months of life.

6. It consists in radical excision of the tumor and the use of an autoplastic flap (subcutaneous and periosteal) as well as in creation of conditions favorable for sufficient and continuous absorption of the excess of the cerebrospinal fluid and regulation of the intracranial pressure.

Use of Hypertonic Saline Solutions in Increased Intracranial Tension.—Henry Cohen (*British Medical Journal,* March 6, 1924), found that intravenous injections of twenty c.c. of a thirty per cent sodium chloride solution resulted in a preliminary burning sensation in the head and almost complete cessation of headache in cases of inoperable cerebral tumor. The relief from the headache continued for periods varying from ten hours to two days and usually an intravenous injection given every third day kept the patient free from headache. The hypertonic saline solution produces some local pain in the tissues and therefore the needle of the syringe should be washed with sterile water and a little of this should be drawn up into the syringe before making the injection. Inasmuch as thrombosis was observed at one time, the author tried giving six five grain tablets of sodium chloride coated with keratin three times a day. This gave some relief.

Results of Surgery for Migraine.—J. A. Buchanan (*Surgery, Gynecology, and Obstetrics,* May, 1924) presents two case histories with the following comment: The histories of the two patients presented illustrate exactly the end results of surgery for migraine. The minor assaults to destroy foci of infection in teeth, tonsils, gallbladder, appendix, and so forth, are all valueless. A new chapter in medicine may be written by surgeons not operating on patients for the relief of migraine. Persons with migraine are not, so far as knowledge is available, exempt from any disease occurring in man. In summing up the author says that migraine is hereditary in man and is transmitted from generation to generation according to the laws of Mendel, and that surgical procedures have no place in its treatment.

Medicolegal Notes.

ACTION FOR MALPRACTICE IN TREATING FRACTURED ULNA—INSUFFICENT EVIDENCE OF NEGLIGENCE.

In an action for malpractice in the treatment of a fracture of the ulna in the plaintiff's right forearm at about the juncture of the middle and upper third, it appeared that for six weeks after plaintiff left the hospital he suffered no unusual pain. The defendant then removed the cast, manipulating the arm a little and bent the elbow, and told plaintiff he thought the union would get hard enough to enable him to go to work in about four weeks. Three days later the arm gave him some trouble and he went to another doctor, Dr. Ryan, who, after reducing the swelling and tenderness, sent him to the hospital for the purpose of removing the Lane plate which defendant had applied to the ends of the bone with two screws. The plate was found to be loose and the bones were dislocated, or they had slipped, permitting the bones to override slightly. The plate was removed, the bones placed in apposition, holes drilled in the end of each fragment, and they were tied together with kangaroo tendon. Dr. Ryan, who was the plaintiff's only medical witness, testified that with the plate in the face of the infection the arm would not heal, and he therefore removed the plate. Plaintiff remained under Dr. Ryan's treatment for six months.

The Iowa Supreme Court, Thorpe v. Talbott, 196 N. W. 716, affirming judgment for the defendant, held that under the undisputed evidence negligence was not shown. Dr. Ryan, a physician and surgeon of experience, did not criticize anything defendant did except to express a general opinion that in the ordinary general run of fractures at this location of the forearm, two screws would not be sufficient to hold the plate in position. But on cross examination the witness testified that the number of screws that should be in the Lane plate is largely a matter of judgment upon the part of the physician who has the wound open before him and observes the character of the fracture, whether it is an oblique fracture or a transverse fracture, or whether it is a fracture that is so broken that the ends dovetail together.

Dr. Ryan also testified that he found an infection and drained the pus; that he could not determine what caused the infection. If the plate became loosened it would irritate and aggravate the condition. He testified that the aftertreatment of a fracture of this kind was rather a difficult question to answer, but said that in a general way the aftertreatment of fracture of the ulna, as well as all fractures, is to observe and examine them frequently, and ascertain, as far as possible, the condition of the fractured bone and limb, and make every effort possible to maintain the reduction as it was reduced, which, however, in some instances cannot be done. The aftertreatment would really consist in watching the dressing and the splints, and seeing that they were giving proper support, and readjusting them, etc., if it became necessary. This evidence practically covered the case, and the witness said that he could not say there was any unskilful treatment. The result is not in itself evidence of negligence, nor does the mere failure to care raise a presumption of negligence.

CHARITABLE HOSPITAL HELD LIABLE TO PAY PATIENT FOR NEGLIGENCE OF SERVANT IN OKLAHOMA.

The Oklahoma Supreme Court, in City of Shawnee, v. Rousch, 233 Pac. 354, approving the doctrine laid down by the Alabama Supreme Court in Tucker v. Mobile Infirmary Association, 191 Ala. 572, holds that a paying patient in a hospital conducted by a municipality may recover damages for injury done her through the negligence of attending nurses administering to her during an operation, "leaving the creation of exemptions of this sort to the legislative department of government, if it deems them expedient." The negligence charged in this case was the administration of an enema of which the solution used was so hot as to burn the patient.

WHETHER FRACTURE IMPACTED HELD FOR JURY ON CONFLICTING EVIDENCES.

In an action for malpractice in failing to use the x ray and fluoroscope in the treatment of an unimpacted fracture of the left femur, because of which a shortening of the plaintiff's leg was not discovered in time to avoid a second operation, there was undisputed evidence that an unimpacted fracture requires these aids to determine whether a shortage is taking place, but the evidence conflicted as to whether the fracture was impacted or unimpacted. The Washington Supreme Court held, Howatt v. Cartwright, 222 Pac. 496, that it was for the jury to decide whether the fracture was impacted or unimpacted.

CROSS EXAMINATION OF MEDICAL EXPERT AS TO EXPERIENCE.

The Circuit Court of Appeals, Third Circuit, holds, Jacoby v. Kelly, 296 Fed. 590, that where, in a personal injury case, a medical expert called by the defendant was examined concerning an alleged injury to plaintiff's liver and on cross examination he voluntarily introduced the subject of the kidney, it was not prejudicial to defendant to cross examine him upon his experience in injuries to the kidney, and the cross examination was relevant upon the question of the qualifications of the witness as an expert.

PHYSICIAN TESTIFYING FROM EXPERIENCE CANNOT BE IMPEACHED BY MEDICAL WORKS NOT RELIED ON BY HIM—NEW JERSEY LAW.

It is the rule in the New Jersey courts, that when a physician testifies from his own experience as an expert, he may not be impeached by medical works upon which he has not relied as authority for his testimony. It is only when a witness refers to them as an authority for his own opinions that they are receivable as evidence, and then only for the purpose of contradicting him. In a case originating in the Federal District Court for New Jersey, the Circuit Court of Appeals, Third Circuit, holds that in administering New Jersey law a federal court is governed by the New Jersey rules of evidence, unless there is a federal rule to the contrary. In this case, however, the federal rule is the same as the New Jersey rule.—Western Union Telegraph Co. v. Ammann, 296 Fed. 453.

APPOINTMENT OF DISINTERESTED EXPERT WITNESS BY COURT.

In an action for personal injuries, the Washington Supreme Court, Hansen v. Sandvik, 222 Pac. 205, holds that it was proper to deny defendant's application for the appointment of a physician to examine certain x ray plates of the injuries to plaintiff's skull, which had been taken by her personal physician, where the x ray plates were examined by a disinterested physician appointed by the court. The picture taken by plaintiff's personal physician was in the nature of a private communication between the physician and his patient which, until waived by being introduced in evidence by plaintiff, could not be used by the defendant.

It was also held proper to deny defendant's application for the physical examination of plaintiff by a physician of defendant's own selection, the court having, in its discretion, appointed a disinterested physician to make such examination.

And Now---for the Weak and Convalescent,

with the heat and humidity of the Summer months at hand, the value of a reconstructive tonic as efficient in action and as palatable and pleasant in effect as

Gray's Glycerine Tonic Comp.

(*Formula Dr. John P. Gray*)

becomes more apparent than perhaps at any other time of the year.

It is in the case of the elderly and infirm—especially those whose digestive organs are inactive and need aiding—that this tonic has shown its superiority to other restorative remedies.

Medical men who derive their greatest satisfaction from the success of the remedies they employ, will find that Gray's Glycerine Tonic Comp. will give them uniformly gratifying results as a tonic restorative when other measures prove to be uncertain and disappointing.

A liberal amount for testing the foregoing will be sent to any practitioner on request

Valentine's Meat-Juice

In **Typhoid, Gastric** and **Other Fevers,** where it is **Essential** to **Sustain** the **Patient** without **Irritating** the **Weakened Digestive Organs, Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** of **Restoring** and **Strengthening** when **Other Food Fails.**

J. R. Wood, M. D., *Physician Sheltering Arms Hospital, Paint Creek, W. Va., U. S. A.:* "I have been using VALENTINE'S MEAT-JUICE in the treatment of Typhoid Fever cases in the Sheltering Arms Hospital, for the last two or three weeks, with the most gratifying results both to the patient and physician. I consider it the best preparation of animal food I have ever seen, in fact, the only one I have ever had any success with."

Dr. Genevaix, *Assistant Surgeon-Major, First Class, Hotel Dieu, Creusot, France:* "The patients to whom I have given the excellent preparation, VALENTINE'S MEAT-JUICE, have found their general condition rapidly improved by it, and in the convalescence from continued Fever (Typhoid and Para-Typhoid) it gives the best results."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
Richmond, Virginia, U. S. A.

VALENTINE'S PREPARATION
NUTRIO PERMIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

Clemenceau as Physician.—An editorial by Dr. Francis R. Packard in *Annals of Medical History* for December, 1919, outlines Georges Clemenceau's medical activities in this country. Soon after his graduation in medicine from the University of Paris in 1865, he sailed for the United States and settled in New York, where he opened an office and added to his meagre earnings by teaching French in a girls' school in Stamford, Conn. He was the seventh doctor in lineal succession in as many generations of Clemenceaus. The young physician had been imprisoned in France because he took part in a republican demonstration of students. Dr. Packard believes that his probable reason for coming to this country was to seek freedom from political oppression after his release from prison. His thesis, *De la Génération des Eléments Anatomiques,* was published during his residence in New York, and it is thought that he sent copies to some of the prominent members of the medical profession in the hope of gaining their interest and aid toward a career. "The thesis," writes Dr. Packard, "shows evidence of great industry and scientific research, but of course the progress of embryology has relegated the views propounded in it to the limbo of forgotten things." A copy in the library of the College of Physicians of Philadelphia bears on its flyleaf an inscription to Weir Mitchell from the author. Clemenceau was married to a student in the school in which he taught, Miss Plummer, of Sanbornton, N. H. They were divorced after twenty years of married life. When the French Empire fell, Clemenceau returned to his native land. Dr. Packard wonders, if this political event had not occurred, whether Clemenceau might not have remained in this country and built up a New York practice.

The Sensitiveness of Flowers.—In the persistent and unremitting search for scientific knowledge one is continually encountering discovered facts that test our credulity and would have been put aside as unworthy of a moment's consideration by our grandparents. Experiments made at the *Jardin d'Acclimatation de Paris* has demonstrated that flowers are almost as quick to show signs of displeasure as human beings. Most people know what it is to arrange two kinds of blossoms in a vase and then to find a few hours later that the blooms are drooping. In most cases this is due to the fact that flowers object to being associated with one another. Separate the blossoms and, in a short while, they will be as fresh as ever.

Lilies of the valley are hardly ever happy for long when mixed with other flowers and soon show their dislike by drooping badly. Roses, carnations, sweet peas, and mignonette are all flowers which should be kept to themselves. Either they will affect the blooms with which they are placed or they themselves will quickly fade.

Quite a number of flowers dislike music. Time and again it has been noticed that blossoms on a piano which is frequently played last only a very short while. Even more curious is the effect of a jazz band on some of the more sensitive flowers. The large Easter lilies and cyclamen have been noticed to turn away from a band which was playing dance music, just as if they wished to get as far off from the sound as possible.

There seems to be something about certain persons that violets really dislike, and not only will they withhold their perfume but they will droop as well. Much the same kind of thing has been observed in the more delicate sorts of roses.

Flowers, as well as foliage plants, often show a marked dislike of certain rooms in a house. A vase full of drooping blossoms removed to another apartment will undergo a complete transformation in an hour or so. There is usually no very clear reason why this should be so, except that, in the first instance, the flowers are not pleased with their surroundings. If a foliage plant seems to be unhappy in one room, place it in another, and it is quite likely to become healthy once again.

Alastrim.—Reference to a disease prevalent in the West Indies may not be devoid of interest, especially as cases have been imported into France, and an instructive communication has been made to the Paris Academy of Medicine, by Dr. Léon Bernard. This disease, which bears the name of alastrim, is an eruptive fever, and appears to have been imported from South Africa where it has been known since 1904 by the name of caffre fever. The onset is sudden, with a temperature of 39° to 40° C. (102° to 104° F.) and digestive disturbances. The fever lasts hardly forty-eight hours, then drops to normal, the gastrointestinal symptoms subside, and the exanthema appears. The latter symptom constitutes the entire symptomatology, there is no exanthema or adenitis.

The exanthema is general, appearing first on the face, scalp, and ears, then on the limbs, most marked on the hands and feet; the eruption is more discrete on the trunk. It may present several successive outbursts, as in varicella. The elements of the eruption are from the onset opalescent vesicopustules of variable dimensions. In the coherent types they are small, but in ordinary cases they are the size of a pea, and are distinct from each other. Some are umbilicated, others not. Pruritus is sometimes present. At the end of ten or eleven days the eruption fades, while sixteen days later it is seen merely as small whitish spots, contrasting by its depigmentation from the surrounding integument. The surface of the spots is often furfuraceous with distinct contours. On the palms—whose skin is white—each element is marked by a pinkish finely epidermized macule surrounded by an elevated epidermic border with a small central spot. Some of the maculæ are confluent, in which case a large surface of epidermis is raised, recalling the desquamation of scarlet fever. The cutaneous lesions require about three months to disappear.

Generally speaking, the disease appears to be mild, although Moody observed thirty deaths out of a total of three thousand cases. Dr. Bernard, who studied cases of alastrim in French ports, states that it is quite distinct from both variola and varicella, although some observers consider the disease as an attentuated form of variola, similar to the varioloid occasionally developing in vaccinated subjects. In this respect, the disease is being studied.

An Effective Remedy *for* Nervous Sleepless Patients

Neuronidia

Palatable Well-Tolerated Reliable

Allaying Restlessness and Producing Refreshing Sleep

Especially indicated in insomnia from mental strain, neurasthenia and other neuroses; also an excellent sedative in sea-sickness.

United States Leads in Chemical Research.—Figures compiled for the *Journal of Industrial and Engineering Chemistry*, by Professor E. J. Crane, of Ohio State University, show that leadership in chemical research, captured from Germany during the world war is still held by scientists in this country. Germany, France, and Belgium have come back strong; but have not yet regained their prewar productivity. Austria and Russia have been slower in recovering from the setback. British chemists have maintained a steady productivity and made a slight gain, while Japan is becoming an increasingly important country in chemical investigation. Czechoslovakia, Poland, Roumania, and China, have recently taken a place among the producers of chemical research. Professor Crane's figures are based on the number of articles appearing in chemical journals of the various countries. In 1913 the German journals published 6512 chemical articles and the American 3940. In 1923 the relation was reversed; the American journals publishing 6014 and the German 5064.

Health of the Swedish Nation.—The complete investigation of personal health records extending back through several generations and covering a whole nation has been undertaken by the Swedish Institute of Racial Biology, which has just turned in the report of the second year of its work.

Under Professor H. Lundberg, who organized the institute, anthropological statistics have now been gathered concerning 83,427 persons. Stature, head measurements, colors of eyes and hair, diseases, especially hereditary diseases, causes of death, etc., are among the things observed by the investigators. In the northern provinces of Sweden, where Lapps, Finns, and Swedes have intermarried, the death rate is relatively high. Special genealogical studies have, therefore, been undertaken in this region in order to ascertain, if possible, what effect race mixture has on longevity. In three villages, for example, genealogical histories have been drawn up for the entire population covering a period of 125 years. In another community the histories of 1,200 families have been traced during the period 1781-1851. Another subject that at present occupies the attention of Professor Lundberg and his assistants is the ancestral history of twins and triplets.

Research into the histories of families is greatly facilitated by the unusually accurate parish registers which have been kept and preserved for hundreds of years, and also by the fact that the entire history of any given family is usually confined to Sweden. There has been almost no increase of the population through immigration, and the Swedes are said to have preserved greater racial purity than any other Teutonic people. Incidentally, it is shown by archeology that the history of the present inhabitants of Sweden goes back 5,000 years in the same place.

The accumulation of data regarding hereditary disease, the development of criminal instincts, and other traits is only a part of the program of the Swedish Institute of Racial Biology. It is also conducting research work into the elimination of racial taints through eugenic measures. Research is also being directed into the field of eugenics and the development of individual talent and genius.

Chronic Diseases*

A Neglected Community and Institutional Problem

ERNST P. BOAS, M.D.,
AND W. H. LIVINGSTON, M.D.,
New York

In its provision for the sick and infirm the community has planned well for certain types of patients. Those who are acutely ill receive excellent care in the general hospital. Those suffering from the lesser infirmities of advancing years are well provided for in proper homes for the aged and infirm. Between these two extremes, however, there is a vast category of individuals of all ages, afflicted with a great variety of pathological conditions which may affect any organ of the body, and which constitute the socalled chronic diseases. The distinguishing feature of these diseases, as their name implies, is their long or even lifelong duration.

Many of these patients require months of treatment to achieve rehabilitation; others are left with a permanent nonprogressive disability; and in still others the downward course is slow but progressive, lasting many months or years. The protracted duration of the disability results in a continuous financial drain on the patient and his family, often ending in complete destitution. In these patients, therefore, the economic and medical factors are closely interwoven, far more so than in the case of the ordinary acute medical or surgical illness. Therefore, in planning for the institutional care of these individuals, a wide variety of questions must be considered. The scope of the problem is indicated by the many different types of institutions that at present meet some of the needs of chronic patients. Homes for incurables, almshouses, city infirmaries, homes for the aged, and hospitals for chronic diseases all minister to the same general class of individuals. But in no case has the problem been envisaged in its full extent, and in no instance has an institution endeavored to determine the relation of its particular small job to the question as a whole. The patient with a chronic ailment is a sick man for whom the proper type of institutional relief has not as yet been provided.

A recent survey of the leading institutions for chronic patients, most of which call themselves homes for incurables, reveals that they largely ignore the scientific study of disease, minimize the importance of medical treatment, are deficient in the provision of a skilled nursing staff, and do not attempt the economic rehabilitation of the patient. A large number of the type of patients under discussion are inmates of almshouses. An analysis of the 1910 census shows that of 84,198 paupers enumerated in almshouses, 53,619 were suffering from a serious physical or mental defect. There were 17,486 deaths. The high death rate is accounted for only in part by the advanced age of the inmates, for 7,803 deaths occurred in patients under sixty years of age, and 3,213 in those under forty. That conditions have not changed much in the last ten years is shown by the New York State figures for 1921, from which it appears that sixty-seven per cent. of the 8,732 inmates of almshouses were sick or infirm.

The object of this communication is to outline a plan for the proper institutional care of the chronic patient. A chronic disease may be defined as one that lasts for a period of from three months to several years. The disease may be checked, it may remain stationary after producing a certain amount of disability, or it may progress until the patient's death. All chronic diseases at the outset require active medical care, either for diagnosis or treatment. If the disease runs a progressive course, active medical care and skilled nursing may be needed until death. Even when the disease becomes stationary, active medical and nursing care may be necessary at any time, should a complication or an exacerbation of the illness occur. If the disease remains stationary or the improvement is sufficient, hospital care may no longer be required.

It will be well to particularize a bit in order to make the question at issue more concrete. All chronic patients may be grouped in three classes according to the demands they may make on the resources of an institution. Class A are those who need active hospital care for diagnosis and treatment; class B are those who need good nursing care only; class C are those who need custodial care only. The management of each of these groups is a problem in itself and each class places different demands on institutional resources.

*From Montefiore Hospital for Chronic Diseases.

Copyright, 1924, by A. R. Elliott Publishing Company.

In seems wisest, therefore, to subdivide an institution that cares for chronic patients into two main subdivisions: the hospital division for the care of class A and class B cases, and the custodial division for the care of class C cases.

HOSPITAL DIVISION OF THE CHRONIC INSTITUTION

The proper care of group A patients demands a complete hospital organization with an attending staff, on which all of the specialties are represented—a resident staff, a good laboratory, x ray and operating room equipment, skilled nursing and dietetic management. Since physiotherapy is one of the best forms of therapy in chronic ailments, the importance of such a department cannot be overemphasized. It should be complete in every respect and should include a Zander gymnasium, divisions for hydrotherapy, electrotherapy, baking and massage. There should be a staff of trained physiotherapists with a trained physician in charge.

Since the treatment of most chronic diseases may last from several months to several years, it is wise to establish an occupation therapy department. The chief function of this department is to occupy the patient's mind by giving him something to do during his long stay in the hospital building. This department should be a branch of the rehabilitation department in the custodial pavilion. which will be discussed subsequently.

A few examples of chronic diseases which practically always place the patient in class A are diabetes, tuberculosis, cancer, severe anemias, advanced heart and kidney disease, recent hemiplegias, chronic polyarthritis, and certain skin diseases, such as pemphigus.

Group B cases do not require the constant supervision of a physician but they should command an excellent nursing service. Examples are patients who are bedridden as a result or brain or spinal cord disease. Bed sores must be prevented, occasional medication must be given, the patient must be fed, cleaned and kept comfortable. Adequate care can be given only by one well trained in the art of nursing.

CUSTODIAL DIVISION OF THE CHRONIC INSTITUTION

This section of the chronic disease hospital is best provided for by a separate building, specially designed. It should be connected with the hospital division by a covered passageway or tunnel, so as to afford convenience of transfer between the two sections. Since custodial cases require no hospital care, the expense of maintaining them should be considerably less than that of group A and group B cases. The custodial case needs merely a home where he may obtain his meals and lodging and perhaps some assistance with his personal needs, such as dressing, washing and feeding. Examples of such cases are old walking hemiplegics, patients with chronic arthritis, multiple sclerosis, advanced but compensated heart disease, tabetics, and patients who have had amputations of one or more limbs. These patients are institutionalized because their home conditions are so poor that their families cannot care for them. For instance, a wheel chair patient who lives in a tenement, will remain confined to his room for the rest of his life; there is no way of transporting him upstairs and down.

The establishment by the community of an adequate number of beds for custodial cases is of importance for the sake not alone of the patients but of their relatives as well. Such an individual frequently disrupts and pauperizes his family. A possible breadwinner is compelled to stay at home to minister to his wants and a constant series of extra expenditures are involved in his care. In addition to this the presence of a chronic invalid, who often is querulous and exacting in his demands, slowly but surely undermines the morale of the family and encourages the acceptance of economic defeat.

It is most important to recognize that patients do not remain in one class indefinitely. Many patients of the custodial class experience relapses or intercurrent affections, which place them in the same category as class A patients. Every class C patient who dies is a class A case during his terminal illness. Provision must therefore be made for their ready transfer to wards where they can properly be cared for. On the other hand, many patients who are on admission class A become in the course of months purely custodial cases. It is a wanton waste of funds to house such subjects in a costly hospital plant when their needs can be met much more inexpensively.

It is the failure to differentiate these different types of patients that is at the root of most of the evils connected with the present institutional care that is given to chronic patients. It is generally assumed that all of these sufferers require custodial care only, that medical treatment and all measures of rehabilitation are useless and, therefore, an unnecessary expense. This tacit assumption is shared by the private homes for incurables, by public almshouses, and by many city infirmaries alike. A survey of their patients, however, reveals quite a different story. It is obvious that unless all chronic patients are admitted into a properly equipped and organized institution, A and B cases cannot receive the medical and nursing care which they need. It is these cases that are so often neglected in the homes for incurables, almshouses and infirmaries. These institutions have little justification for an independent existence. They should function as the custodial pavilions of hospitals for chronic diseases.

The internal construction of both the hospital and custodial pavilions of the institution must be adapted to the needs of the patients; for example, many chronic patients propel themselves in wheel chairs, which means wide corridors and halls, wide doors to the rooms and wards. Side railings along the walls and in the bath rooms are indispensable to certain patients. Because chronic patients remain in the institution for months or perhaps several years, a reasonable amount of social life should be provided. Therefore, space should be set aside for a theatre, library, recreation rooms, barber shop, tailor shop, a cooperative stationery store, etc.

When the condition of a class A or B patient has improved to the extent that he no longer requires hospital care, efforts should be made to discharge him, providing his social condition warrants it. The patient who is burdened with no physical disability or with only a very slight one, can easily shift for himself even if he is homeless. The physically handicapped individual, however, should not be discharged, both for his own sake and that of his fam-

ily, unless they are well able to take care of him. All patients who cannot be discharged because of economic reasons should be retained in the custodial pavilion.

Once they have been admitted to the custodial pavilion, the attempt should be made to rehabilitate them from an occupational viewpoint. Every custodial patient who can should pursue some gainful form of work. Besides earning something toward his support, work will keep him in a happier state of mind; his health may further improve, or the stationary condition of his ailment may be prolonged.

The rehabilitation department should consist of an experienced director in charge and a staff of assistant teachers. After obtaining from the physician all medical information regarding the patient's ailment in relation to work, e. g., length of work period, outdoor or indoor work, manual or mental, etc., they should assign and teach the patient the proper occupation. Only useful occupations, by means of which a patient may partially or entirely support himself, should be selected. Examples of group C patients who can pursue gainful occupations in the custodial pavilion, are those who have had one or both lower limbs amputated or paralyzed, certain types of joint diseases, certain heart cases. These patients are unable to walk about the city streets or have no chance to compete for a position with the healthy man. The work must be obtained for them and brought to them. Certain chronic pations may learn some form of occupation in the rehabilitation department, which will, in the course of time, enable them to procure employment and leave the institution.

At Montefiore Hospital for Chronic Diseases where facilities for A, B and C cases are provided and where a cross section of the patient population is practically identical with that of homes for incurables, infirmaries and almshouses, we have made a study of the relative number of these different classes of patients. Such a study, if accurate, will give some basis for future planning for this type of institution. Such figures can never be absolute, for there will always be some difference of opinion as to the proper category in which to place the patient. In our experience physicians err most frequently by placing in the custodial class patients who really require more careful attention. Because of the fact that patients often change from one class to another, it was thought best to note the number of hospital days provided in each category. At the end of every month the resident physicians entered on a card which had been made out for each patient the number of days during the past month which that patient had been in each of the classes, or, if his status had not changed, in one particular class.

The results of a seven months' analysis are presented in the following table:

TOTAL NUMBER OF HOSPITAL DAYS, JUNE TO DECEMBER, FOR THE YEAR 1923

	Cancer		*Medical*		*Surgical and Orthopedic*		*Neurological*	
A	5,812	95.5%	10,201	47.8%	13,651	64.3%	15,143	30.3%
B	274	4.5%	4,401	20.6%	3,974	18.7%	19,270	38.6%
C	0	0%	6,735	31.6%	3,607	16.9%	15,479	31.0%
	6,086		21,337		21,232		49,892	

PERCENTAGE OF A, B AND C CASES

FOUR SERVICES		TUBERCULOSIS SERVICE		
A	45.5%	A	20,542	69.5%
B	28.3%	B	1,239	4.2%
C	26.2%	C	7,767	26.3%
			29,548	

The table shows that nearly fifty per cent. of the hospital care days belong to group A and that almost seventy-five per cent. of the hospital care days are in groups A and B. This is sufficient evidence for the need of proper hospital facilities in any institution that pretends to take care of chronic diseases. The percentage of class A patients is somewhat higher than would be found in the average institution that cares for patients with chronic diseases, for Montefiore Hospital endeavors to admit only such patients as will be benefited by medical care. On the other hand it must be recalled that there are very few institutions in existence which will admit class A patients. The general hospitals will not keep them, for the course of their illness is too long; the homes often will not take them for they require too much attention, or else are not sufficiently disabled. A striking case in point is patients with early arthritis deformans. If treated early the progress of the disease may be checked in many instances. This the general hospital refuses to do and the home cannot do. Consequently these patients drift from hospital to hospital, from dispensary to dispensary, becoming progressively worse, until they are sufficiently crippled to be suitable candidates for admission to a home for incurables. The same may be said for many other diseases. The state of affairs existing in most institutions accepting chronic diseases has already been alluded to. The doors of the general hospital are locked to the chronic patient, while the institutions that will admit him do not treat him as a patient.

There are many homes for those with incurable cancer, institutions which provide only elementary nursing care for their patients. Yet we find that ninety-five per cent. of our cancer patients belong to class A. It is true that not many of these unfortunates can be cured, but many can be relieved and, in not a few instances, their lives can be prolonged for a considerable period. Many physicians have seen individuals with cancer of the rectum or of the uterus, sick, emaciated, suffering and helpless, who, after appropriate radium or x ray treatment, have regained their strength and their spirits and have lived for several years in comparative comfort.

The problems which we have briefly outlined need study from every angle. The medical problems are inextricably bound up with economic ones. A young child with severe diabetes, who requires constant insulin and dietetic treatment, can be cared for at home, if the family is well to do, or even if the family is just selfsupporting, provided that the parents are intelligent. If they are ignorant, however, the child is doomed unless it is brought up in an institution. A case requiring nursing care only could be provided for at home in many instances, were it not for the fact that the home care of such an individual keeps a necessary wage earner from his work while he is caring for the invalid. A hemiplegic

patient, who is up and about, will never see the sunlight or enjoy a breath of fresh air if his family live on the third floor of a city tenement.

Measures should be taken to ascertain the number of beds for chronic patients that are needed per unit of population. These should be further subclassified in the different categories that have been discussed. The adaptation of the physical plan of the buildings to the several types of patients should be thought out. An analysis of the necessary medical services and equipment demanded by the different types of patient must be made. For instance, the great importance of physiotherapy will bear emphasis. The nursing, dietetic, social service, laboratory and occupation therapy services will have to be studied in relation to the needs of the different groups of patients.

The importance of a properly conducted hospital for chronic diseases in the education of physicians and nurses cannot be overestimated. These diseases form the bulk of the ailments to which humankind is heir, and they have not as yet received the intensive study which they merit. Similarly, the opportunities for the clinical and laboratory investigation of chronic diseases in such an institution are unlimited. At present most of this valuable material is going to waste, instead of being used in an endeavor so to increase our knowledge of disease that its end results—the chronic patient— may no longer be a community burden. The care and disposition of the chronic patient and the scientific study of chronic diseases are among the most important community and medical problems of the present generation.

Radium Therapy in Gynecology*

P. BROOKE BLAND, M.D.,
Philadelphia, Pa.

(*Concluded from page* 107)

RADIUM IN UTERINE MYOMATA

More and more, radium is finding a legitimate place in the therapy of uterine myomata and, as aptly remarked by Beclere: "The treatment of uterine fibroids is quite legitimately passing from the hands of the surgeon to the medical radiologists and from year to year it will thus pass in increasing proportions."

We have been using radium in the treatment of uterine myomata since 1916. We have used discriminating care in the selection of our cases and thus far we have radiated seventy-seven patients. The results have been gratifying in nearly all.

In most instances a dose ranging from twelve hundred to twenty-four hundred mghrs. was used. In all but four patients a single dose was sufficient to control the bleeding and cause regression of the tumors. Four patients required more than one exposture. One patient with a tumor as large as a five months' gestation requred three applications. In another, three exposures were necessary before the bleeding ceased. In still another there was no abatement of bleeding after three exposures, and therefore a vaginal hysterectomy was performed. The fourth patient had what we regarded as a large myoma. Three twelve hundred mghr. doses were administered, but the symptom, bleeding, was not relieved and an abdominal hysterectomy was subsequently performed. The microscopic examination of the specimen removed from this patient revealed the myoma to be undergoing sarcomatous degeneration.

In one of the patients to whom we have already referred and upon whom a vaginal hysterectomy was done, the tumors were extremely small and even after microscopic analysis, the cause of the continued bleeding could not be determined.

With respect to diagnosis, it is well to direct attention to its importance as well as its difficulties. Radium should not be applied to a myoma unless the radiotherapist is certain of the true nature of the lesion. Sarcomatous degeneration occurs in approximately from one to two per cent. This alteration cannot be determined clinically and while myomata generally present a fairly characteristic clinical picture, mistakes, nevertheless, may occur. Recently we removed a large ovarian cystoma from a patient who had been radiated for a myoma by one of our prominent contemporaries. Quite recently I radiated a patient for menorrhagia ostensibly rising in a uterine myoma. The menorrhagia ceased, but a tumor, later recognized as a highly organized ovarian cystoma, was present in this patient's pelvis. This was removed subsequently through an abdominal incision and it proved to be a teratoma which originated in the right ovary.

Historically, it is of interest to note that the first application of radium within the uterine cavity in the treatment of uterine myomata, was administered by Dr. Robert Abbe in 1905.

The treatment of menorrhagia, due to myomata, by radium was started in the Mayo Clinic in 1915 and at the present time radiation is considered the treatment of choice in growths of moderate size, regardless of age, although between the ages of thirty and forty, or during the childbearing period, myomectomy is given first place, and radiation second place.

This course is pursued because the menstrual and reproductive functions are more likely to be conserved by operation than by radiation. This is confirmed in the report of five hundred and ten myomectomies performed in the Mayo Clinic from January, 1898, to 1918. This report shows that thirty, or 12.1 per cent., of the patients operated upon became pregnant subsequently.

On the other hand, it has been demonstrated that

*Presented at a regular meeting of The Bucks County Medical Society, February 13, 1924.

it is rather unusual for women to conceive and continue to term after radiation. According to Stacy, the literature records but few instances of conception going to maturity after the application of the element. This writer has observed but one instance of postradiation conception and this patient aborted a dead fetus at the end of the seventh month. Myomectomy, then, in the childbearing period seems preferable to radiation.

INFLUENCE UPON CONCEPTION AND PREGNANCY

H. B. Mathews refers to eight hundred and seventy-four patients of the childbearing age to whom radium was administered. Of this number only thirty-nine conceived. Twenty of these patients gave birth to normal babies at full term. In fifteen, labor occurred prematurely.

Werner records fifteen hundred cases of myomatous and myopathic bleeding in which seventeen of the patients became pregnant, several of them repeatedly. In all there were twenty-four cases of gestation; nine of these terminated in abortion, three of which were unquestionably induced. Fourteen pregnancies went to full term; one patient had a hysterectomy performed; six patients, even after several months of amenorrhea, conceived and in several patients oligomenorrhea only developed.

It is interesting to note the nature of the full term deliveries. Of the fourteen full term children born alive, four died, one immediately after birth and three at the age of one year of acute infection. The other children were sixteen per cent. below normal weight and eight per cent. below normal height. What significance this may have it is impossible to say, though it does seem to indicate that children thus born are subnormal physically.

It might be of interest to cite the cases of two patients who were treated during pregnancy. In one case four irradiations were given. The child born of this mother was of normal development. In the second case, four applications were made within the vagina and the child of this mother was born at full term, but it was far below normal.

Werner believes that irradiations may cause injury to the ovum or embryo, but that the injury may be of such nature as not to be a permanent handicap and that it may be overcome during the course of subsequent development.

Kupp has been employing intrauterine radium therapy since 1914 in the treatment of uterine fibroids. He reports four hundred and fifty-two patients who were irradiated, of whom three hundred and thirty-eight had myomas and one hundred and twenty-two some form of metropathy. In forty-three young women there was a marked diminution in the size of the tumor with the return of menstruation after one year. Six of these patients became pregnant, went to term and gave birth to healthy children.

RESULTS

Dr. Howard A. Kelly in a personal communication states that he always considers radium first in the treatment of myomata and operation second. Radium, he says, "is the best treatment in women forty years or over or when the menopause is not far distant." He is convinced that in nine cases out of ten, radium will do all that operation can do without the attendant risk of the latter. As a preliminary to the use of radium, Dr. Kelly emphasizes the importance of excluding all possibilities of malignancy and lateral disease. All doubtful cases should be given the benefit of surgery. In small tumors occurring in young women, Kelly prefers myomectomy because this does not check the menstrual process nor preclude the possibility of conception.

In 1919, Kelly reported two hundred and ten cases of uterine myomata treated by radiation. One hundred and forty-six of these patients were forty years of age or over and sixty-four were under forty. The average age was forty-three. The oldest patient was sixty-seven and the youngest twenty-six. Basing his conclusions on one hundred and eighty-two of the two hundred and ten cases, he found radiation sufficient to relieve the patients in all but eleven. In five of the eleven there were other complications. In two, operation was elected. In three, operation proved unnecessary and only one patient failed to respond to treatment.

From observation of more than one hundred cases and from the viewpoint of efficiency, safety and morbidity, Clark states: "that within certain limitations one may say with positive assurance, that radium must supplant operation in the treatment of uterine myomata."

Clark, like other radiotherapists, employs radium only when the menopausal years are not far distant, and then only if the tumor is uncomplicated by adnexal disease and if not "too large."

Clark and Keen in a further study of four hundred and seventy-six cases of bleeding due to myomata and metropathy, controlled the symptom in ninety-one per cent. of the cases. In this series one death occurred, which was attributed to postpartum hemorrhage. In twenty-three patients slight bleeding returned but not of sufficient gravity to call for further care. In twenty-eight patients subsequent treatment was necessary, but of the total number only three per cent. required surgery. Complications were confined to two cases of phlebitis and eight cases of more or less severe neuritis. Clark and Keen believe, as do most investigators, that prior to the age of thirty-five, radium may be used safely, though myomectomy is preferred for procreative reasons.

Miller treated one hundred and seven cases of fibroids with radium. Complete cessation of symptoms occurred in one hundred and two within five months after treatment. Two of the remaining five cases required a second application but obtained relief. Two were not relieved by a second exposure and one patient had a hysterectomy performed.

Polak treated one hundred and six cases of uterine fibroids. In one hundred and four patients the bleeding ceased and never recurred after the first subsequent period. In two patients a second application was made. Operation was necessary in two only.

DOSE

We have already indicated that in young women in whom permanent amenorrhea is to be avoided, the average dose should be small. Usually a dose of two hundred to three hundred mghrs. is quite sufficient. In older women five hundred to six hundred mghrs. or more, may be employed, but Kelly does not think that a dose of more than fifteen hundred

mghrs. is ever necessary. A large dose, however, does not do any harm and in elderly women it is unquestionably better to use a relatively large dose and bring about permanent amenorrhea by a single application. In these patients it is our custom to use one hundred mg. for twenty-four hours.

INFLUENCE OF RADIUM UPON MYOMATA

Without doubt, radium will cause a large majority of uterine fibroids to disappear partially or wholly and in almost every instance it will overcome the most frequent as well as the most vexatious symptom, hemorrhage. These phenomena are brought about in three ways: First, by the action of radium upon the ovaries, causing sclerosis of these organs with partial or complete cessation of function; second, by sclerosis and obliteration of the bloodvessels (endarteritis) supplying the neoplasms with nutrition; and third, by causing direct regression and atrophy of the neoplastic cells.

APPLICATION

In the treatment of uterine myomata the element is applied to the interior of the uterine cavity. It may be applied also, properly screened, over the abdomen. Intrauterine applications may be combined with x rays over the abdominal wall, although the application either with radium alone or with the x ray is seldom necessary (Fig. 3). One dose of the element is usually quite sufficient to cause regression in the tumor and control the symptoms. A second application may be necessary and this may be made after an interval of four weeks, if the symptoms do not abate.

INDICATIONS

The indications for radium in the treatment of uterine myomata may be summed up in the following:

1. In small growths occurring at any age—with certain reservations—if associated with bleeding.
2. In all types of myomata—except the submucous—if uncomplicated by infection of the uterus or its appendages.
3. In large obese women in whom operation is difficult and often associated with a definite morbidity and a definite mortality.
4. In patients who refuse operation.
5. In individuals suffering from constitutional disease.
6. In patients of poor surgical risk.
7. In tumors of moderate dimensions, not exceeding in size a four or five months' pregnancy.
8. In tumors not rapidly increasing in size.
9. In growths not complicated by malignancy.
10. In tumors temporarily to control bleeding and prepare the patient for operation.
11. In tumors uncomplicated by calcification.
12. In tumors free from infection and necrosis.

RADIUM IN MENORRHAGIA AND METRORRHAGIA OF INDETERMINATE ORIGIN IN YOUNG WOMEN

Radiation in intractable uterine bleeding occurring in young women is finding a definite field of usefulness, but the employment of the element in cases of this type must be done with utmost caution. The danger of establishing a permanent amenorrhea or premature menopause should be kept vividly in mind. If excessive doses are used, this unfortunate incident is highly probable, although if small doses are employed, this unhappy sequel is very improbable.

The menstrual flow can be readily modified and controlled by radiation. Small doses may cause the menstrual process temporarily to cease, but reestablishment usually occurs anywhere from a few months to two years. Temporary amenorrhea is caused by the radium destroying the sensitive maturing graafian follicles, while the less sensitive primordial follicles are not affected. We have used it in patients as young as fourteen with excellent results. In one patient of thirty-five in whom a heavy dose was administered the menstrual flow totally disappeared. One menstrual period occurred at the end of one year, but no bleeding was observed thereafter.

DANGERS

The greatest danger in young women, of course, is the establishment, not only of a permanent amenorrhea, but sterility. It has been observed that radium is prone to bring about sterilization, even though the menstrual cycle recurs normally. Conception after radiation is rare and the exception rather than the rule. Only a few full term post-radiation conceptions, as we have already indicated, are recorded in the literature. Why ovarian function apparently continues with relative sterility is inexplainable.

RADIUM IN BLEEDING OF THE MENOPAUSE

For abnormal bleeding of the menopausal years not associated with gross lesions, but due to uterine myopathy, expressed in the terms chronic metritis, subinvolution or uterine fibrosis, radium is preeminently the best agent at our disposal. The application of radium, however, in these cases, indeed as in most others, should be preceded by a diagnostic curettage. Malignancy must be eliminated. Adnexal disease must be excluded also. The bleeding must have its origin in benign lesions of the endometrium or uterine wall. Practically every case can be cured. Application is made withn the uterine cavity.

S. M. D. Clark, of New Orleans, reports thirty-two cases of this type with complete relief in all. Watkins also has had good results in menopausal hemorrhage, though the number of cases he reports is small. Stacy reports two hundred and sixty-three cases of menopausal hemorrhage, some due to small myomas. In one hundred and eighty-five cases, or 70.35 per cent., bleeding ceased. Of this number in only fourteen were two applications required. In most, the bleeding stopped entirely at the end of two months. General improvement was noted in two hundred and thirty-one patients and one hundred and fifty-seven increased in weight. No improvement was reported in sixty-eight. Seven hundred mghrs. or twice the dose used in patients thirty-five years of age and under was employed. A second treatment is given if necessary, any time after the fourth week.

Heyman sums up his experience in the treatment of climacteric hemorrhage, in the Radium Institute of Stockholm, Sweden. From 1916 to 1920, there were treated forty-nine cases of uncomplicated climacteric hemorrhage. All were treated with radium. In forty-one patients a single exposure sufficed to control the symptom. In thirty patients the application was intrauterine and in eleven the element was simply applied against the vaginal cervix. In seven patients two exposures were necessary and in one patient three were given. Amenorrhea was produced

in thirty-two patients and oligomenorrhea in six een. In one patient the treatment was unsuccessful.

Uncomplicated menorrhagia or metrorrhagia, after the age of forty, is exceptional. The appearance of either at this time should always be regarded with grave suspicion and an underlyng pathologic basis, especially malignant disease, should ever be kept clearly in mind.

John G. Clark, in a personal case, had a patient who went to full term, but unfortunately she died of postpartum hemorrhage.

S. M. D. Clark, of New Orleans, reported five cases of bleeding occurring in young women. The youngest patient was seventeen, the oldest thirty-three. In these complete suppression of menstruation occurred in four. In one patient menstruation returned to a normal two day type. The dose was rather large, much larger than generally recommended. It ranged from one thousand three hundred and seventy-five mghrs. to three thousand eight hundred and fifty-nine mghrs.

Stacy radiated one hundred and twenty-two cases of abnormal bleeding occurring in women under thirty-five. Some of these patients had small myomata. Nineteen of the patients were twenty-five or under. Of the one hundred and twenty-two cases reported, ninety-eight of the patients were heard from; the bleeding was controlled in 55.6 per cent.; a second application was required in seventeen. The average dose was two hundred and ninety-three mghrs. In twenty-five patients the periods were reported normal in amount, in eleven they were irregular and scant, and a complete cessation occurred in six of the cases.

Three of the patients, aged twenty-eight, thirty and thirty-four, respectively, received a three hundred mghr. dose. Hysterectomy was performed later in six; one patient (thirty-three years old) eight months after treatment who did not improve; one after one year on account of pelvic pain, although the bleeding had ceased; in another patient who did not respond to treatment and in still another who also failed to obtain relief. In one patient, a girl of sixteen, a hysterectomy was done thirty-three months after radiation on account of continued bleeding. At operation a cancer of the fundus was found. In seven others myomectomy was done because the symptoms were not relieved by radiation. Two of these patients were radiated twice. In young women Stacy recommends enough radium to control the symptom, but not enough to stop functional menstruation. However, there is no definite way to judge the dose. It is best to begin with a small amount and gradually repeat, if necessary, after a three, four or six month interval. In women over thirty-five years of age, larger doses may be used, because during these ages the menstrual process is not so important.

Usually fifty mgs. for fourteen hours with repetition, if necessary, will afford relief. Stacy reports four hundred and seventy-eight cases beyond the age of thirty-five and three hundred and forty-nine of these patients were heard from. The treatment was repeated in sixty-four and operation was done later in twenty. Of these twenty only four required two exposures and two were operated upon before the full benefit of radium was obtained. The results were satisfactory in all.

RADIUM IN ENDOCERVICITIS AND CERVICITIS

Radiation acts most favorably in cases of endocervicitis associated with infection and leucorrheal discharge. The infection is readily overcome and healing of the granular surface is usually quite prompt. All cystic formations usually disappear at the end of two or three months. A. H. Curtiss has had excellent results in cases of this character. H. H. Wiggers noted a decrease in cervical leucorrhea routinely after radiation. Curtiss recommends fifty mg. within the cervical canal from twelve to sixteen hours. Occasionally he found a second treatment necessary. One hundred and twenty-six patients have been treated by Curtiss. Twenty-two could not be followed. Of the one hundred and four patients subsequently studied, ninety recovered, seven improved and seven were not benefitted.

RADIUM IN DYSMENORRHEA

The application of radium is being extended to the treatment of obstinate cases of dysmenorrhea and certainly this simple measure should be chosen in preference to any radical surgical procedure. No type of surgery has seemed to give these patients relief. Dilatation and curettement has uniformly failed. No specific drug has been discovered, so radiation, if used with caution, it is asserted, will produce gratifying results.

The same care and the same law applies to its administration in dysmenorrhea as in bleeding occurring in young women. Only small doses should be used and the interval of application should not be less than three or four months. The possibility of a premature menopause should be kept constantly in mind and the inhibitory influence of radium upon conception should not be forgotten. Radium in dysmenorrhea, then for these reasons, in our judgment should be used only in exceptional cases.

RADIUM IN CARCINOMA OF THE VULVA

The operative treatment of cancer of the vulva has never been satisfactory. We have never seen a patient recover permanently after operation. Radium seems to offer more hope for these cases than does operation. Burnam reported eighteen cases of cancer involving the vulva and urethra with recovery in more than fifty per cent.

RADIUM IN TUMORS OF THE BLADDER

Benign tumors readily disappear. Carcinoma is favorably influenced and in some cases the growths disappear. Recurrence is common in the latter, but even these are sometimes favorably acted upon. The infiltrating type is the most obdurate. In my work I have used radium capsules through the urethra and one patient thus treated has remained well since. In another I used the element through a suprapubic wound, applying fifty mgh. for twelve hours. The local symptoms were ameliorated but, owing to the presence of extravesical extension, the patient finally succumbed. Combined intravesical and extravesical application may be made and the element may be used in conjunction with the x ray.

William Neill, Jr., advocates intravesical treatment by emanation, using 0.5 millicurie of radium emanation to destroy one c. c. of growth. In this way the entire tumor is attacked. The emanation pearls are left permanently in place. They discharge their maximum action by the end of seven days, but continue more or less active for at least twenty-eight days. This intensive plan should not be repeated until after a lapse of two months. Many of the emanation pearls escape with particles of the growth and are discharged during urination.

George G. Smith treats vesical carcinoma along similar lines. J. T. Geraghty uses similar treatment and has found the means most valuable in the therapy of bladder tumors. In malignant disease he found that recurrence took place in thirty per cent. of the cases treated, but in most instances even these responded to treatment. In three very refractory recurrent cases treatment was ineffectual. Geraghty applies from one hundred to two hundred and ten mgs. of radium element. This is applied and held by a special cystoscope to the tumor surface. Applications are made for one hour and are repeated from one to three times weekly, depending upon the size and nature of the tumor and the reaction of the patient. In order to prevent injury of the normal tissues, Geraghty advocates partial distention of the bladder cavity with water. Since this plan has been adopted, radium burns, previously not uncommon, have not occurred.

The results of radiation of neoplasms of the bladder has proved fairly satisfactory. H. H. Young says that even in advanced malignant disease cure is not impossible. Papillomata disappeared readily. Young advised that papillomata first receive fulguration, followed by the application, to their bases, of radium. J. T. Geraghty states that papillomata, both benign and malignant, disappear under the influence of radium, but in the infiltrating type of cancer of the bladder resistance to treatment is quite marked.

RADIUM IN PRURITUS VULVÆ

It has been found that radiation acts very favorably in pruritus and many instances are recorded in which the itching has responded after other measures have failed. One can safely say that pruritus is frequently relieved and occasionally completely overcome by thorough radiation. In some cases the x rays seem to act more energetically than radium, while in others the response is more decided to the latter. In some instances pruritus may be overcome by the use of both x rays and radium, applying the radium directly to the region most markedly affected and the x rays to the general skin surface.

Knox recommends that the x ray treatment be carried out for several weeks and exposure be made once or twice each week. In the application of radium, especially in young women, small doses are used and repeated. Usually the applications are made until a reaction in the skin is noticed. This is always allowed to subside before the exposure is repeated.

CARCINOMA OF THE BREAST

D. J. Quigley treated six cases of Paget's disease of the nipple with radium and four years subsequently four of the patients or sixty-six per cent. were living and well. Direct application was made to the nipple. Fifty mgs. were used with one half mm. of silver and one half mm. of rubber as screens.

Z. A. Johnston uses radium similarly in these recurrent cases. He believes localized recurrent nodules should be treated this way and that thus they will early disappear. In these cases radium is superior to x rays. In larger affected areas the x ray is best, but in these a combination of both may be used.

Johnston believes that all breast cancers show a better surgical outlook if radiated prior to operation, since without this plan in one out of every five so-called early cases, the patients who are operated upon without this plan die. This is true even though there is no macroscopic or microscopic evidence of malignant extension to the axillary lymphatics. He believes, therefore, that every operable breast cancer should have at least one complete series of deep x ray therapy, especially crossfiring about the axilla, supraclavicular region and mediastinum.

It is the custom of Johnston to treat these socalled operable cases with radium packs over the tumor proper and in the axilla, especially if there is any evidence of adenopathy. This is followed in three weeks by the insertion of needles into the growth and in three weeks subsequently, the patient is submitted to the surgeon. This allows a more direct action upon the neoplasm than is the case in a surface application and besides the lymphatics are probably treated at the same time. Removal can be accomplished then, he believes, provided there is no mediastinal involvement, with expectation of permanent cure.

George E. Pfahler has used radium in recurrent localized nodules and lays claim to better results than with x rays, especially those localized along the line of the incision, the supraclavicular and axillary regions. He uses it because application can be brought in direct contact with the nodules. We have used it in similar cases with better results than afforded by the x ray.

RADIUM IN CARCINOMA OF THE RECTUM

A. E. Pinch does not believe it justifiable to advise operation even in comparatively favorable cases of rectal carcinoma when the patient is sixty years and beyond, since by the use of radium life may often be prolonged in fair comfort for four, five or six years. Colostomy, he believes, should be advised in almost every instance because the constant passage of fecal matter over the growth invariably stimulates its activity.

W. J. Mayo has found that radium provides good results in inoperable carcinoma of the large intestine and upper rectum.

G. W. Crile advocates radium prophylactically following radical operation for rectal carcinoma.

We have used radium salts both in a curative and palliative way after colostomy for advanced cancer of the rectum. By this means we have, we feel certain, prolonged life and added both systemic and local comfort to these unfortunate patients.

The author's bibliography will appear in his reprints.

Primary Sarcoma of the Stomach

With a Report of a Case of Myofibrosarcoma

HENRY KLAUS, M.D.,
Weehawken, N. J.
Attending Surgeon, North Hudson Hospital

Although sarcomata of the stomach is relatively infrequent compared with carcinomata, their occurrence is frequent enough to demand greater attention by the surgeon and not be regarded as a clinical curiosity. Their infrequency may be shown by the fact that there is but one specimen of gastric sarcoma in 840 specimens of sarcomata in the Berlin Pathological Institute. Eusterman and Senty report twenty cases at operation at the Mayo Clinic between the years of 1907 and 1921. During this same period operations had been performed on 2,146 cases of carcinoma. Sarcomata are even more infrequent than benign tumors of the stomach, as shown by Eusterman in his report of twenty-seven cases occurring between 1907 and 1921, as against 2,146 carcinomata. Sarcoma was found present in only four cases in an analysis of 928 cases of gastric cancer by Smithies in 1919. In 27,250 abdominal sections at the Mayo Clinic during five years (Masson) there were eight sarcomata of the stomach (quoted by Haggard). Douglas gathered together 227 cases and added three cases himself to the literature. These with the additional cases added by Erdmann, Fischer, Haggard, Basch, Gillette, and Pistocchi, and the one included in this report, make altogether 238 cases of sarcoma of the stomach on record. Of these 116 came to operation, the rest being found at necropsy. The case reported by Pistocchi is interesting as the symptoms followed a severe trauma of the epigastrium, and he is inclined to accept a direct connection with trauma as the causative factor in this case.

FIG. 1.—Specimen showing sarcoma of the stomach.

Sarcomata are connective tissue growths, hence they never develop from the mucous membrane. They may develop from connective tissue, muscle fibre, lymph nodules, or from endothelial cells of the lymph spaces of the stomach. According to their tissue origin they may be fibrosarcoma, myosarcoma or lymphosarcoma and endotheliomata. According to their histological structure they may be classed as either roundcelled or spindlecelled sarcomata. The average age limit is 41.6 in sarcomata in contrast to carcinoma, which is 61.2 (Douglas). Lymphosarcoma occurs earlier than the other forms but is found present more frequently. Sarcomata may involve the entire stomach or form a large mass growing from it. Lymphosarcomata originate from the submucous layer and spindlecelled sarcoma from the muscularis, while carcinomata originate from the mucosa. This point is of significance because it makes ulceration when present in sarcoma a late manifestation. From its gross appearance the roundcelled sarcoma is the type most likely to be mistaken for carcinoma, as it infiltrates and most often involves the pylorus. This type of sarcoma is more malignant and more readily metastasizes. The spindlecelled type is more likely to be circumscribed or pedunculated, presenting itself externally beneath the serosa or internally beneath the mucosa. This type is slow to metastasize, is best to deal with surgically, and offers a far better prognosis. The grafting of sarcoma upon a myoma or fibroma is probably of no uncommon occurrence specially when the benign tumor has existed for a long time. Pyloric obstruction in sarcoma of the stomach is infrequent even in the lymphosarcoma which involves the pylorus, as the pyloric opening is rarely encroached upon although the pylorus itself is greatly infiltrated.

SYMPTOMS

Frequently there is an entire absence of symptoms throughout the course of the disease; this is especially true when the growth is situated in the pars media and when the mucous membrane is not involved. On the other hand, the symptoms may vary from the mildest expression of gastric distress to the severest manifestations seen in gastric cancer. A preoperative diagnosis is seldom made and it is only by gross examination or after careful microscopic examination that a correct diagnosis can be made. The one condition from which it is desirable to differentiate sarcoma is carcinoma. The importance of this arises from the fact that sarcoma is a much slower growing tumor and affords a far better chance for a radical cure in the early cases. Carcinoma, which always involves the mucous membranes, will give rise to more gastric irritation, while sarcoma, as a rule, does not invade the mucosa. Carcinoma also is most commonly situated at the orifices and in the body of the stomach, while sarcoma is found along the curvatures; hence carcinoma is much more likely to give obstructive symptoms. This is a late manifestation of sarcoma, not from an encroachment on the pyloric opening but due to an infiltration of the pyloric ring and stomach walls. In spite of the fact that sarcoma of the stomach does not invade the mucous membrane, there is usually found an absence of hydrochloric acid and the presence of lactic acid and a slight trace of blood, which may be accounted for by the secondary anemia which is always present.

RADIOGRAPHIC EXAMINATION

Although positive diagnosis of sarcoma of the stomach is not possible by radiographic examination, it is the greatest aid we have in making possible a diagnosis of the presence of an operative lesion. The points that favor a positive diagnosis

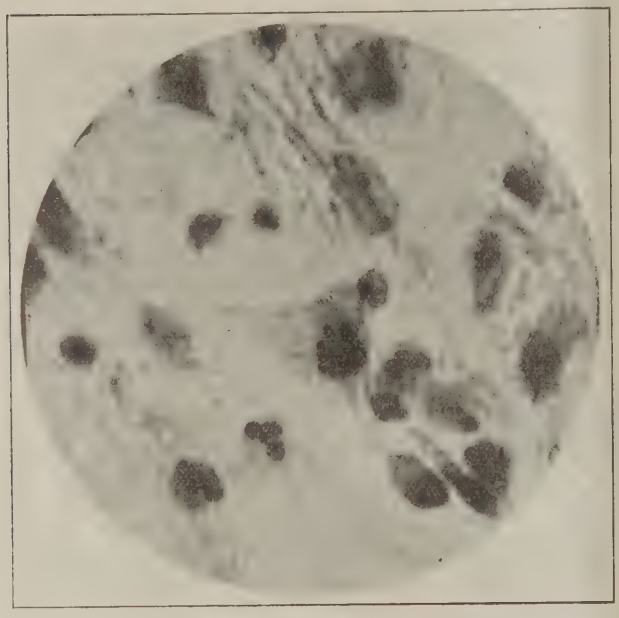

Fig. 2.—Myofibrosarcoma of stomach, section through tumor.

of sarcoma are the filling defect with comparative smooth edges while in carcinoma one is more likely to get irregular outlines in the radiograms.

Case.—W. T., aged forty-nine, watchman, was admitted to North Hudson Hospital August 30, 1923, with but one symptom, namely, marked weakness. This was specially noticeable on exertion, when he became dyspneic. This weakness began about February, 1923, and gradually became worse up to the present. About four months before admission he noticed he was becoming paler, which had steadily increased up to the time of his admission. He had absolutely no other symptoms, no vomiting, no abdominal pain, appetite was good, bowels costive at times, and at various times during the past fifteen years he had suffered from a slight bleeding from small external piles. During the past six months he had lost twenty-five pounds. The interesting thing about this case is the fact that the patient suffered from no gastric symptoms at any time and sought relief for anemia and the associated symptoms of weakness and shortness of breath.

The physical examination was entirely negative, except for a marked secondary anemia. There was no tenderness in the epigastrium, and no mass palpable. Blood examination on admission showed hemoglobin 25 per cent., red blood cells 2,456,000, white blood cells 6,200, color index ½, polymorphonuclears 60 per cent., lymphocytes 40 per cent. September 4, 1923, four days after admission the hemoglobin dropped to 20 per cent. and the red blood cells to 2,000,000, no change in white blood cells or differential count. Feces showed a slight trace of blood with benzidine test, no ova or parasites present. Urine was normal; blood pressure 95-60, blood chemistry normal, Wassermann negative. As yet we were unable to make a diagnosis outside of a marked secondary anemia. A gastrointestinal radiographic examination was decided upon as a routine and much to our surprise a large tumor of the lesser curvature of the stomach was clearly shown somewhat above the pylorus. Dr. H. V. Broeser suggested that this seemed to be a possible benign tumor inasmuch as the radiograms showed the presence of rugæ which are not usually seen in carcinoma. This was more emphasized in the fluoroscope as the tumor (endogastric) could easily be pushed about and was easily movable. In spite of these findings the diagnosis did not seem to conform with that of benign tumor in the presence of such marked anemia. Stomach analysis showed free hydrochloric acid absent, slight lactic acid and a slight postive benzidine.

Blood transfusion was given on September 10, 1923, one thousand c.c. given, which brought his hemoglobin up to 30 per cent. and red blood cells to 3,200,000. There was again a slight fall of the hemoglobin and red blood cells during the next few days reaching 25 per cent. and 2,776,000. A second transfusion was given September 17, 1923, following which the hemoglobin rose to 55 per cent. and red blood cells to 4,976,000. One thousand six hundred c.c of blood was given. Inasmuch as this man's only symptoms were due to anemia following the transfusions, he was entirely free from symptoms and felt perfectly well.

Radiographic examination by Dr. H. V. Broeser, September 5, 1923, showed at the fluroroscopic ex-

Fig. 3.—Myofibrosarcoma of stomach, section through tumor.

amination no hindrance or adhesions at the under surface of the flexures. Colon normal in contour and mobile. Cecum ptosed. Malted meal drink disclosed stomach of the orthotonic type, axis oblique with a large defect on the lesser curvature. No peristaltic waves, yet striæ were seen, mobility good.

pylorus irregular. The duodenum was at right of median line, normal in shape and size.

A diagnosis of tumor on the lesser curvature, pars media, was made. A possibility of its being benign was based on the mobility and stria.

Operation was performed on September 19, 1923. Medium epigastric incision was made under block anesthesia (local). General anesthesia was begun after opening the abdomen. On exploring the abdomen a large endogastric tumor the size of an orange was found arising from a fairly large base from the lesser curvature and the posterior gastric wall about three inches above the pylorus. The mass was well up under the left costal margin and for this reason was never felt preoperatively. The mass was freely movable within the stomach. The peritoneum covering the base of the tumor was

FIG. 4.—Radiogram showing practically complete emptying after four hours. Taken four weeks after operation.

smooth and normal in appearance but at the upper edge of the base of the growth toward the cardia there was considerable infiltration as the tumor mass merged into the normal gastric wall. On first examination the mass gave one the impression of being a large benign fibroma but on close examination of this infiltration a diagnosis of fibroma which has undergone a sarcomatous degeneration seemed certain. There was no metastasis present in the glands along the lesser or greater curvatures nor in the liver or retroperitoneal. The case seemed very satisfactory for a resection and ultimate cure. A pylorectomy was done according to the Billroth type II method with a posterior gastroenterostomy. About two thirds of the stomach was removed. Convalescence was smooth and uneventful. The patient was discharged from the hospital on October 14, 1923. Radiographic examination showed a small remnant of the stomach with a good functionating gastroenterostomy and the stomach emptying itself practically completely before six hours. On discharge his hemoglobin was 62 per cent. and red blood cells 4,468,000.

Pathological examination by Ward J. MacNeal, P. Klemperer, E. Morgan.

The specimen was the lower portion of the stomach including the pylorus. Stomach wall was 75 mm. along the lesser curvature and 100 mm. along the greater curvature. In the interior of the stomach was a fungoid mass sixty-five by seventy mm. in diameter and attached to the wall of the stomach by the pedicle, forty-five mm. in diameter. The surface of the mass was somewhat smooth but on the pedicle it was velvety. On section the tumor mass was found to be solid and resilient. The cut surface was light gray and opaque for the most part, but there are orange yellow patches, six to thirteen mm. in diameter, not sharply outlined.

Sections showed the gastric wall close to the tumor allowing a definite distinction of the coats of the wall. The glands of the mucous membrane were regular in size and shape. The membrane propria was rich in lympoid cells, scattered among which plasma cells and a few polymorphonuclear leucocytes might be found. In the deeper part of the mucosa occasional small lymph follicles were seen. The muscularis mucosa was sharply defined, and showed a few areas of round cells. The mucosa consisted of loose areolar tissue, blood and lymph vessels and nerves and contained a few areas of lymphatic infiltration. The subserous connective tissue was thickened and showed slight roundcell infiltration. In the adjacent fat tissue there are several lymph follicles and diffuse infiltration by lymphocytes and plasma cells.

The tumor compressed the mucosa. The glands became scarce and the corium contained more leucocytes and a considerable number of Russell's bodies. The muscularis mucosa could hardly be recognized. The submucous layer was greatly thickened. It had not the structure of loose areolar tissue, as described above, but was filled by a growth which was rather sharply defined from the mucosa but not the muscularis. This growth was composed of large spindle-shaped cells which were surrounded by delicate and coarse fibres which, in part, formed interlacing bundles. Among these cells there were others which were cylindrical and contained a prismatic nucleus. The arrangement of these cells was very loose, particularly in the superficial areas of the tumor, and many polynuclear leucocytes and lymphocytes could be found in the meshes. There were also lymph follicles which were found surrounding small blood-vessels. In the deeper parts near the muscularis areas could be found where the cells became more polygonal and their cytoplasm filled with vacuoles. Here the tumor cells infiltrated the muscular coat. The muscle bundles were pushed aside and compressed by the invading cells.

Special stains were applied to ascertain the nature of the tumor cells. In Van Gieson stain the spindle-shaped cells were surrounded by fibres which took the red stain, whereas the cells with the rodlike nuclei took a distinct yellow color. Therefore, the former could be considered as connective tissue cells

and fibres; the latter, however, had muscular elements. The polygonal cells with the vacuolized cytoplasm showed in Soudan stain preparations a great number of deeply red stained globules which in part filled the cells. In examination with the immersion lens occasional mitotic figures could be found.

A diagnosis of myofibrosarcoma was made.

Examination of the patient eight months after operation showed him to be in excellent health. Up to the time this article was written there had been no evidences of a recurrence. He had gained sixty pounds in weight, had no gastric symptoms, no abdominal pain. Hemoglobin ninety-five per cent., red blood cells, 4,800,000.

SUMMARY

Sarcoma of the stomach occurs in about one per cent. of all stomach tumors. It is less frequent than benign tumors. The average age incidence is 41.6 years in contrast to carcinoma which is 61.2. Lymphosarcoma occurs earlier than the other forms, and is found more frequently. Lymphosarcoma is more apt to be infiltrating and more prone to ulceration than the spindlecelled or myosarcoma but not nearly so frequent as carcinoma. Spindlecelled or myosarcoma is more apt to form a large endogastric or exogastric tumor. The pylorus is less often attacked or obstructed than in carcinoma. Metastasis also occurs less rapidly than in carcinoma, whereas myosarcoma is even less prone to metastasis than the lymphosarcoma. The prognosis of lymphosarcoma is bad. Of twelve cases reported from the Mayo Clinic the operative results were as follows: Six were inoperable for resection; in the six with gastric resection two patients died after operation from peritonitis, one returned four months later with a recurrence, one returned with a recurrence five months later, one returned seven months later with a recurrence, and the last patient was operated upon too recently to be considered. These cases, however, were all of the lymphosarcoma variety. Myosarcoma and fibrosarcoma are far more favorable even than carcinoma.

435 Palisade Avenue.

A Prophylactic Gas Filtering Ventilator for Summer Autumnal Coryza and Asthma*

GEORGE N. JACK, M.D.

Buffalo, N. Y.

There is now accumulated enough clinical and scientific data to enable us to consider the relation between gases and sickness. The unstable blood of the asthmatic is hypersusceptible and highly sensitized to hematolytic gases.

"Nearly all varieties of gases and many combinations can be found upon the ground in certain localities and at certain seasons of the year; some originating from the ground itself, some from stagnant water, as swamps, some from animal excreta and some from the decomposition of animal and vegetable matter. Among the ground gases are found the carbon, chlorine, bromine, sulphur, ammonia, phosphorous, oxygen, nitrogen and hydrogen group combinations" (1).

In a final analysis many hematolytic gases come from putrefying proteins and they do not all reach the blood by inhalation but often are absorbed from the intestine. Putrefaction generates a hematolytic gas as shown by the sudden death of second day silo fillers or during the wilting and putrefying stage of recently cut corn. This is also demonstrated by the sudden death of those entering sewers. Fermentation generates a blood stabilizing alcoholic gas as shown by the fact that after the cut corn in the silo ferments, the silo is not only safe but a stimulating and invigorating place to enter.

The end metabolic products of all living animals are either hematolytic gases or substances that rapidly generate hematolytic gases. Growing vegetation under the influence of daylight absorbs carbon dioxide and hematolytic ground gases and gives off blood stabilizing gases, such as oxygen, which are not only beneficial but an immediate and vital necessity to animal life.

In order partially to protect my asthmatic and summer autumnal coryza patients from hematolytic ground gases, I have constructed a gas filtering ventilator. This gas filter contains charcoal, calcium chloride, zinc oxide, magnesium silicate and sodium bicarbonate and is designed mostly for organic vapors, ammonia, sulphur and acid gases and those that the lime will absorb or neutralize. If used for automobiles, oxide of manganese and copper should be added to destroy carbon monoxide or auto exhaust gas as they are used in the universal gas mask for this purpose (2). Automobiles, trains and street cars should install gas filtering ventilators as they not only filter out poisonous gases but they prevent chilling from draughts.

DIRECTIONS FOR MAKING GAS FILTERING VENTILATOR

The size and construction of these gas filtering ventilators will depend upon the space to be ventilated, size of window, etc. An efficient size for a bedroom is three by twelve by twenty-seven inches, or of a length to fit the width of the window.

The lumber used in making the frame is one half by two inch material.

The size of the copper wire screen box when completed is three by twelve by twenty-seven inches or a length to fit the width of the window.

First, make a frame two by twelve by twenty-seven inches.

*Read at Chicago before the American Allergy Association, June 10, 1924.

Second, make two frames out of the one half by two inch lumber for copper wire covers, size on outside, twelve by twenty-seven inches.

Third, tack copper wire on the two cover frames.

Fourth, nail on the inside copper wire screen cover.

Fifth, fill the box half full of charcoal.

Sixth, add the desired chemicals which in this case are unslaked lime, zinc oxide and magnesium silicate (powdered talc) and sodium bicarbonate, made into a pasty emulsion.

Seventh, finish filling screen box with charcoal.

Eighth, screw on outside screen cover.

Ninth, make two slide wood bolts, size one half by two by seven inches with a slot one quarter by three inches in middle for two screws with washers.

Tenth, screw the slide bolts on each end and outside half of top side of screen box; slide bolts to hold screen box in window.

Extra: When desired, a frame or tube may be attached to the inside of the gas filtering ventilator for an electric fan to give forced suction ventilation.

Asthmatics whose unstable hypersusceptible blood is highly sensitized to summer autumnal night ground gases should, if residing in the country, protect themselves by the following simple precautions:

1. Select a house on as high a hill or mountain as possible with a gravel soil and away from swamps, stagnant water or cess pools, outhouses, barns or manure piles. The cellar should be dry, clean and well ventilated.

2. Select for the bedroom, the highest room in the house.

3. Install a gas filtering ventilator in the bedroom window.

4. Have no carpets or straw mats on bedroom floor.

5. Select a single iron bed with fine, woven wire springs.

6. Use clean, freshly aired woollen blankets for mattress, covering and pillows.

7. Purchase ten pounds of unslaked lime and put it in ten one quart basins, then set them on the bedroom floor. These ten basins full of unslaked lime may be stacked up in a closet during the day. The lime must be stirred occasionally to keep the unslaked lime at the top, and when all slaked, thrown out and replaced by new. The unslaked lime absorbs blood disintegrating gases and gives off blood stabilizing gases as chlorine. Hence limeworker's immunity to tuberculosis. Two quart pans of coarse salt should also be kept in the bedroom for the same reason.

Chlorine is an element normally found in the blood, and chlorine gas in physiological doses has a blood stabilizing action. The steam from slaking lime benefits some asthmatics.

A simple method for administering the chlorine and lime dust treatment is to stir up the lime in the pan. One tablespoonful of sodium chloride (common salt) added to one only of the ten quart pans of unslaked lime will, together with the other nine pans of unslaked lime without salt, generate all the chlorine gas that the asthmatic can stand and at the same time enough to benefit him. If salt were added to more than one of the ten pans of unslaked lime and kept in a closed bedroom at night, it might generate an overdose of chlorine gas. The unslaked lime in the ten one quart pans should be stirred up with a big spoon every night as they are taken from the closet, unstacked, and set upon the bedroom floor. A good way to separate the slaked lime from the unslaked lime is to sift it over in a large eight quart pan through a sieve or ordinary kitchen colander.

Vedder and Sawyer use chlorine gas as a therapeutic agent in common colds, coryza, rhinitis, pharyngitis, laryngitis, bronchitis, whooping cough and influenza. They state that, "Employees in plants producing or using chlorine have always believed themselves free from respiratory diseases. This was brought to our attention because, during the war, when the chlorine plant at Edgewood Arsenal was producing to full capacity, the great influenza epidemic struck the post and the hospital was filled to overflowing. It is stated that no cases were recorded among the operatives of the chlorine plant, although every other organization on the arsenal had its full quota of cases" (3).

Chlorine gas in therapeutic quantities would tend to prevent influenza in two ways; first, by adding stability to the blood, and second, by crowding out, keeping away or diluting blood disintegrating gases.

Chlorine gas from a tank or inhaling apparatus as used for colds should not be used on asthmatics or those afflicted with summer autumnal coryza.

8. Keep the atmosphere in the bedroom at a blood stabilizing temperature, humidity and light. The temperature should be about seventy degrees and the humidity about sixty-eight. Have no pipeless kerosene or gas stoves in the room nor smoky lamps. The best light is an electric light which should be kept burning all night, especially if the patient is asthmatic, as light adds stability to the blood. The best heat would be that of the open wood fireplace, as many blood disintegrating gases are rapidly combustible and would thus be burned up or carried out the chimney.

9. Never have cut or potted plants in the bedroom.

10. Saltpetre should be kept in the bedroom and if the patient is asthmatic, it should be burned on retiring and during the night as it generates a blood stabilizing gas and one that reduces the viscosity of the blood and favors expectoration.

11. It is well, when possible, to have a tank of oxygen on hand for an emergency. The gas or ozone produced by violet rays has a blood stabilizing action that has benefited some asthmatics who have generators in their bedrooms.

12. When possible, an electric fan should be in the bedroom to be used on hot, humid nights.

13. Various blood stabilizing and capillary tonic gases can be liberated or generated in the room from volatile substances such as camphor gum, pure grain alcohol, dried coniferous leaves or needles and dried eucalyptus leaves. The alcohol should be placed in two saucers, half an ounce in each. At first I tried oil of eucalyptus and oil of turpentine in place of the leaves, but I found that some gases that were not hematolytic as large doses of gas from some volatile oils as oil of turpentine, would, through their depressing or paralyzing action upon the cardiovascular system, produce a cardiovascular dyspnea, which, if severe, would result in an asthmatic, hematolytic crisis.

14. Asthmatics should sleep alone.

15. Asthmatics, on dewy or foggy nights, should retire to their gas filtered bedroom as soon as the dew falls and should not leave it in the morning before sunrise, unless they wear the United States Universal Army Gas Mask. If riding out, they should ride in a closed vehicle equipped with a gas filtering ventilator. The aim is to keep blood disintegrating gases out of the asthmatic's bedroom, to add blood stabilizing gases to it and to keep it at a blood stabilizing temperature, humidity and light. It is not intended as a treatment for asthma.

My observations of prevailing blood disintegrating meteorotelluric phenomena during certain epidemics of sickness are as follows:

GROUP I

1. Diminished sunshine from a shortened day, day shorter than night, cloudy, partly cloudy or hazy weather.
2. Day temperature of about 86°, followed by cool, heavy dew nights.
3. High humidity or relative humidity above 68.
4. Stale, windless, atmospheric stasis.
5. Hematolytic, atmospheric gas accumulations.
6. Diminished atmospheric magnoelectricity, elasticity and absorption.
7. Atmospheric pressure comparatively or regionally low or falling.

This group is associated with summer autumnal coryza, asthma, cholera infantum, cholera morbus, dysentery, eczema, heat retention or heat exhaustion.

GROUP II

This is the same as group one, except with a day temperature below 60°, followed by chilly or freezing nights.

This group is associated with grippe, influenza, whooping cough, asthma, bronchitis, rheumatism, measles and diphtheria.

GROUP III

This is the same as group two, except with a comparatively or regionally high or rising atmospheric pressure. This group is associated with pneumonia and asthma.

Osler (4) says that "It is by no means confined to the poorer districts, but occurs in the houses of the better classes, particularly when the plumbing is defective." This statement shows an association between sewer gases and diphtheria. Malarial fever and asthma are associated with swamp ground gases; Dengue fever, malarial fever and asthma with semitropical swamp and ground gases; yellow fever and asthma with tropical ground gases. Coryza and asthma occurring in the spring-summer season are not as severe or epidemic as the summer autumnal types and are associated with a moderate degree of Group I, except diminished sunshine from the shortening day.

These observations show that hematolytic gases constitute an important etiological factor in the production of much sickness and disability. The world war showed that gases constituted an important etiological factor in asthma, as many soldiers who were not asthmatic before their war gassing were rendered asthmatic by it, and have been asthmatic ever since.

Gas from burning sulphur will bring on an attack of asthma more quickly than anything else, by increasing the viscosity of the blood and causing a dyspnea which if severe, will soon terminate in an asthmatic hematolytic crisis. Hematolytic gas, as carbon monoxide, will produce a fatal hematolysis more quickly than any other known substance. Clinically, hematolytic atmospheric gases do not produce any local irritation to the mucous membranes when they are inhaled, but immediately upon entering the blood they produce chemical disturbances or disintegrations that throw the blood out of equilibrium. In order to regain its equilibrium, the blood dumps its disintegrated material along the line of least resistance, producing coryza, asthma, vomiting, diarrhea or eczema. The dumping of the disintegrated material with its acidosis is what causes the irritation.

A study of 1,351 cases of asthma and summer autumnal coryza during the last twenty-nine years has convinced me that certain gases, especially summer autumnal night gases, have a sufficient blood disintegrating action to constitute one of many etiological factors.

Asthmatics and summer autumnal coryza victims residing in a well paved and sewered city, on going into the country during the summer autumnal season to stay overnight on a windless, heavy dew, ground gas accumulating night, frequently have their asthma and coryza aggravated or precipitated. This group can go into the same country during the same season and stay overnight on nights when blood disintegrating ground gases are less prevalent, as dewless nights, very windy nights or nights with a heavy, constant rain, without any unusual disturbance. Day trips into the country during the same season do not aggravate this group, unless the trips are made during a drought on a day which has had a short shower, generating blood disintegrating ground gases and fog similar to a dewy night.

Hematolytic gases are increased at night through an absence of sunheat, sun electromagnetism and sunlight, increased humidity and also due to the fact that vegetation sleeps at night which prevents its absorbing ground gases. Hematolytic gases are increased during the summer-autumn equinoctial season, or from August 11th to November 6th, due to the shortening day, the cooling of the summer heated earth and the wilting or decomposing of ripe or cut vegetation. They are increased also during the winter-spring equinoctial season or from February 4th to May 5th by a thawing of the winter frozen earth, which liberates ground gases before vegetation has begun to grow and absorb them.

Ground gases are increased in swampy sections and in semitropical and tropical lowlands. Night ground gases are more prevalent in the open country than in a well paved, sewered and lighted city.

Many asthmatics in the country have asthma only during the seasons of the year when ground gases are increased, or in a city residence where sewer gas is markedly prevalent as near sewer openings or disposals, or where sulphuric acid gas from burning coal accumulates. Hematolytic atmospheric gases are diminished by a scattered population, altitude, low humidity, sun, wind, electromagnetism, good atmospheric absorption, dry, rocky, sandy, gravel or alkaline soil, a frozen surface of the earth, oceans, large lakes and deserts.

The fatal blood disintegrating action of certain

ground gases when sufficiently concentrated is demonstrated by the sudden death of those going down into some wells or certain mines, or death from inhaling natural fuel gas. Mild manifestations are demonstrated by the chills and fevers of those working in deeply excavated trenches and the chills and fever of plowmen.

The threshing of mouldy grain liberates a hematolytic gas. After one day's threshing of mouldy grain at my farm in the fall of 1915, five out of a crew of ten threshers had their blood disintegrated by the gas from the mouldy grain or "were gassed." This gassing was clinically manifested during the following night by chills, fever, headache, nausea, coryza and dyspnea with chest pains or the symptoms of grippe, influenza and bronchial pneumonia.

Freshly cut, wilting, drying and curing vegetation, such as hay, grain, corn, vegetable tops, flowers and weeds, give off hematolytic gases that often produce coryza and asthma, and if they are allowed to mold or putrefy they give off hematolytic gases that may produce coryza, asthma, pneumonia, or influenza. The gases used in the world war produced coryza, asthma, bronchial pneumonia, influenza or eczema, regardless of existing meteorotelluric conditions. Ordinary atmospheric hematolytic gases, except the swamp and tropical gases, do not contribute to the production of epidemic sickness, unless they are accompanied by the meteorotelluric phenomena mentioned in Groups I, II, and III.

Some gases that are not hematolytic will indirectly produce a hematolysis in several ways. Three of which are: 1. Shutting off the supply of oxygen by their irritating action, producing a congestion of the mucous membranes of the respiratory apparatus, as chlorine in concentration, the acid gases or the phosphorus and sulphur derivatives. 2. Crowding out oxygen by too great a dilution, as too much nitrogen. 3. By the production of putrefactive products through death of tissues, owing to a vesicent or blistering action, as that of mustard gas.

Most acid gases except those resulting from fermentation are both caustic or vesicant and hematolytic. An acid soil generates acid ground gases and an alkaline soil generates alkaline blood stabilizing ground gases. Some irritating or secretory nonhematolytic gases, such as the brominated compounds, will produce lachrymation, sneezing, rhinorrhea and dyspnea, but not genuine coryza or asthma unless this disturbance results indirectly in a hematolytic crisis.

The chief and most essential element in the production and maintenance of life and health is gas. Variation in the gas supply is a frequent contributing cause of sickness and death. The easiest and quickest death is that caused by gas. Those who have been rendered unconscious by automobile exhaust gas state that they had no warning of danger or feeling of discomfort.

Blood disintegrating gases seek their lowest level, the same as water, thus settling in valleys or lowlands. The higher the altitude, the fewer blood disintegrating gases are found. At an altitude of seven thousand feet, practically no hematolytic gases are encountered and no gas hematolytic crisis occurs with the resulting sickness as summer autumnal coryza, uncomplicated asthma, malarial fever, dengue fever or yellow fever.

The weather bureau in its daily reports of meteorotelluric phenomena should include atmospheric electromagnetism and the atmospheric gas composition. Wind, like the sun, has a blood stabilizing action. It blows away blood disintegrating humidity, and hematolytic atmospheric gases and increases the atmospheric electromagnetism.

The winter of 1923 and 1924 in Buffalo was a steady, even, cold winter. The ground was continually frozen and covered with snow most of the time. Strong winds prevailed with good atmospheric electromagnetism, good atmospheric absorption, medium humidity, clear white or blue skies with an unusual abundance of sunshine.

The constantly frozen earth lessened the formation of ground gases and the winds prevented their accumulation. As a result of these blood stabilizing, meteorotelluric phenomena, there was but little sickness, consisting mainly of mild epidemics of nerve exhaustion, nausea, flatulency and diarrhea. Some had a violent diuresis in place of diarrhea. We escaped our usual epidemics of pneumonia, grippe and diphtheria. When the ground thawed during the spring equinoctial season, the ground gases were liberated, resulting in blood disintegrations which were manifested clinically as epidemics of mumps, measles, tonsillitis, colds, coryza, asthma, boils, scarlet fever and whooping cough.

Good atmospheric electromagnetism is manifested by white morning skies, poor sound vibrations, poor telegraphic and radio vibrations, the rapid absorption of moisture, sparks from stroked fur, increased energy and activity. Excessive atmospheric electromagnetism tends to produce nerve exhaustion. Sending electric currents through the air, as by radio, probably tends to increase the atmospheric electromagnetism. The aeroplane has a disturbing influence upon atmospheric phenomena that will necessitate the restriction of its use.

A scientific fact never changes. The ancients recognized in the region of swamps a morbific effluvia floating in the atmosphere as a product of the decay or putrefaction of animal or vegetable matter that produced sickness with chills and fever or malaria which they called a miasm; but now, with our knowledge of gases, these socalled swamp miasms can be identified and classified as definite hematolytic swamp gases.

Some of the ground gases which have been recognized, their composition determined and that we are very familiar with are natural fuel gas used in lighting and heating our houses or heavy carbureted hydrogen, olefiant gas or ethylene, fire damp or light carbureted hydrogen, stagnant pool gas where vegetables are undergoing putrefaction or carbureted hydrogen, choke damp or carbonic acid gas and the deadly carbon monoxide found in some mines, wells, or silos and formed whenever carbon is burned with an imperfect supply of oxygen. In the ordinary city with its numerous manufacturing plants, nearly all known hematolytic gases are prevalent inclding sewer gas, carbon monoxide, sulphuric, phosphoric acid, the natural fuel gas, and illuminating gas.

In lowland cities during foggy, windless, humid, chilly, smoky weather the city hematolytic gases are very evident.

Clinically, there is no specific cause that produces

the unstable blood of the asthmatic or that disintegrates it to produce an attack of asthmatic dyspnea, but a combination of causes. Likewise there is no specific treatment or prevention, but its treatment and prophylactic measures must be applied as indicated.

There are numerous agents and combinations that will disintegrate the unstable blood of the asthmatic sufficiently to produce an attack of asthma, many of which come under the following classification: 1, hematolytic atmospheric gases; 2, putrefactive products, obtained through food, water, overeating, retentions or accumulations; 3, meteorotelluric phenomena, and 4, humidity, accompanied by either a hot, chilly or freezing temperature.

Among the numerous causes of summer autumnal coryza, the two chief are hematolytic atmospheric gases and heat humidity retentions. Disturbances from blood disintegrating atmospheric gases, when accompanied by certain weather conditions, result in numerous manifestations that vary from those due to the blood being thrown slightly out of equilibrium with the resulting headache to a severe meteorotelluric, physicobiochemical, hematolytic crisis or influenzal death.

Foreign Bodies in the Esophagus with Report of Six Cases

JOSEPH FRIEDMAN, M.D.,
And SAMUEL D. GREENFIELD, M. D.,
Brooklyn, N. Y.

Before the days of endoscopy the question of foreign bodies in the esophagus was of necessity a more or less speculative one. The physician often had to depend largely upon the veracity of the patient's statements or those of the parents. This suggests the possibility of error in diagnosis.

Some of the saddest pages in surgical annals are filled with cases of foreign bodies in the esophagus. We can readily appreciate the untold difficulties with which operators had to contend, when we consider the insufficient and inadequate appliances and instruments used and today regarded as most unscientific and dangerous. In those cases where it was definitely decided that a foreign body was lodged in the esophagus and the symptoms were sufficiently urgent, the external approach to the esophagus exposed the patient to the great dangers of such an operation, injury to important structures and the risk of infection. Where the patient survived the operation and was fortunate enough to escape infection a prolonged period of convalescence was required.

Fig. 1.—X ray of patient in Case III, showing the shadow of the button.

Then we have a large number of cases in which the foreign body became lodged in the esophagus and in which bold attempts were made to force the intruder downward into the stomach. For the accomplishment of this bouginage and the stomach tube were employed. In a small number of cases this procedure proved effectual. However, in many instances there resulted irreparable damage to the esophagus with subsequent death. Laceration of the esophageal walls was followed by violent and fulminating esophagitis and periesophageal inflammation. Perforation of the muscular coats resulted in mediastinitis and mediastinal abscess which rapidly proved fatal. A foreign body that originally only entered the mucosa as a result of instrumentation was forced through the esophageal wall and in several instances produced hemorrhage from perforation of the aorta. In cases where the foreign body was not recognized and was therefore permitted to remain a long time, there resulted necrosis and infection with suppuration extending to the trachea with consequent edema and asphyxia.

Today we are fortunate in having at our disposal the x ray and fluroscopy, and with the newer methods for examination and extraction the procedure is now rendered safe and certain.

There are certain factors, however, that govern the prognosis in cases of foreign body in the esophagus. The first factor that comes to our minds is that of location along the swallowing tube. This is not of such vital importance to the esophagoscopist. No matter where it is lodged it can easily be detected and grasped. Nevertheless what is of greater interest is the relation of the axis of the foreign body to the axis of the esophagus thus influencing the physiological action of the latter. We can readily understand that a foreign body situated so that it will permit of passage of none or little food, will give rise to more disturbing symptoms. The patient's attention is called quickly to the seriousness of the condition and medical aid is sought early. However, where the foreign body is of such a nature that it will occlude the esophageal lumen only partially and so permit overriding of food, deglutition is not interfered with to a great extent and patients are likely to defer seeking medical advice. It is this delay that influences the prognosis in many cases. Only after complications make their appearance do these patients consider their condition.

This then brings us to a second consideration that influences the prognosis, e. g., the length of time that elapses from the date of inception of the foreign body to its discovery and removal. Its presence will exert pressure upon the esophageal walls and produce necrosis of the tissues. Where the patient is fortunate enough to avoid immediate infection with sloughing and perforation there results hyperplasia and thickening from nature's effort to protect the surrounding tissues. This hyperplasia later, even if the foreign body is removed, organizes and gives rise to stenosis of the esophagus, a condition which is intractable and requires prolonged treatment. If the foreign body is not removed, it ultimately causes death.

A matter of vital importance influencing the prognosis and one which even at this late date does not seem to be recognized sufficiently is that the best and safest route for a foreign body to leave the human economy is the way it entered. The mortality in esophagus cases seems to be directly proportionate to the amount and extent of previous futile and harmful instrumentation. The blind attempt at forcing the intruder downward is most unscientific, dangerous, and in many instances results in irreparable injury and many of the socalled simple cases of extraction have been so rendered difficult and complicated. The majority of complications can all be traced to such faulty and indiscriminate procedures. Therefore it may be stated that the prognosis is far better in cases where no tampering has been done..

The last factor, one which to our minds is the most important and upon which depends the ease of extraction, the possible complications that may develop and lastly the outcome, is the character and shape of the foreign body. It is evident that sharp pointed foreign bodies, such as chicken bones, pins, and others, can easily penetrate the esophageal mucosa and occasionally the muscular coats, and in consequence become more or less fixed thus producing direct injury to the esophagus. The etiology of all subsequent infections and complications can thus be traced. When the mucosa or submucosa are injured there results an acute phlegmon at the site of injury. The submucous variety being the more common type. This form usually remains localized and the patient recovers. However, when the foreign body is of such a nature that it penetrates the esophageal wall, then there results the socalled periesophageal or mediastinal abscess to which the patient rapidly succumbs.

The six cases we are reporting were seen during the past two years. Each case has been selected from our series because of some special interesting feature connected with each particular one.

Case I.—Mrs. R., aged sixty-two, swallowed a chicken bone on the evening of January 11, 1923. Immediately following she complained of a sensation of choking and fullness and gradually pain made its appearance. That same evening she saw a physician who attempted to force the bone downward using his finger. These maneuvers were rewarded with added pain and vomiting of blood. The patient spent a miserable night and the next morning her condition seemed to be much worse. Swallowing of solids was impossible and that of fluids was associated with sharp pain in the anterior of the thorax and in the back on the same level. The patient was referred to us the next morning, and examination of her throat disclosed some redness. The larynx was normal. With such a typical history we deemed it advisable to send the patient to the hospital. An x ray was taken and the bone located midway between the cricopharyngeal and aortic constrictions.

Extraction the same day at 4 p. m., time three minutes; local anesthesia. A size 10 Kahler Brunning esophagoscope was introduced and upon entering the esophagus below the cricopharyngeal constriction the mucous membrane on the post esophageal wall was found to be markedly reddened and edematous. Pressure against this mass caused an expression of a foul smelling pus which seemed to exude from the uppermost point of the swelling. After swabbing and drying the field, the point of the chicken bone came into view, but the bleeding soon obscured it. Again drying the area the foreign body was plainly visible projecting into the lumen of the esophagus, the other end being held fast in the esophageal wall. With alligator forceps the intruder was grasped and extracted. The entire swelling seemed to have disappeared. An application of twenty-five per cent. argyrol was made and the patient put to bed. Nothing was given by mouth for twenty-four hours, after which the diet consisted only of fluids for another forty-eight hours. The patient seemed to be immediately relieved. On the third day her temperature was normal and deglutition was not accompanied by pain. On several occasions we reesophagoscoped the patient and so followed the progress of healing, which was complete in ten days. She left the hospital at the end of two weeks, cured.

It is evident in this case that the foreign body pierced the esophageal wall but did not perforate. About its lodgement there resulted an acute phlegmon. The timely recognition of its presence and early removal prevented the more diffuse inflammation which may have caused death of the patient, as will be exemplified in the next case.

Case II.—Mrs. E. R., aged sixty, swallowed a fishbone on April 19, 1923. She immediately resorted to the usual household and oldfashioned remedies such as producing emesis by tickling the throat and also swallowing dry bread. These were of no avail and she saw her family physician who treated the condition more or less lightly. However, he inserted the stomach tube on several occasions with no relief. Three days elapsed before we saw her again, at which time the following was noted: she was an obese woman and suffered from diabetes. She complained of severe spontaneous pain anteriorly on a level with the unciform cartilage and sharp lancinating pains in the back at the same level. The act of deglutition was not associated with pain until after the food began its course downward; apparently until it reached the site where the bone was lodged and then the patient noted exacerbation of her pains and she vomited. Nothing but liquids could enter the stomach and this with difficulty. The history was typical, and the patient was admitted to the Beth Moses Hospital on April 12, 1923. At time of admission the temperature was 101, pulse 100, respiration 28.

Extraction under local anesthesia, time four minutes. The No. 14 Kahler Brunning esophagoscope was introduced and at about twenty-five cm. from

the teeth margin the fishbone was seen running transversely across the lumen of the esophagus. The surrounding esophageal tissue was swollen and edematous but there was no evidence of an actual phlegmon at this location. Only that part of the bone extending beyond the forks was visible, the remainder being buried in the esophageal wall and the other end protruding possibly into the mediastinum. With alligator forceps the bone was grasped and extracted but with some difficulty, the forks of the bone having fixed it firmly in the esophageal wall. There was little bleeding and the area was swabbed with twenty-five per cent. argyrol. The patient was put to bed, the diet restricted to fluids after twelve hours and the esophagus medicated with a mixture of bismuth glycerine. The patient did not seem to be very much relieved after extraction. The pain was severe with deglutition. Her temperature on the three successive days rose to 104 and she appeared acutely ill. On the morning of the fourth day she had a profuse hemorrhage following which she went into shock. She rallied after several hours complaining of marked dyspnea and cyanosis. The patient succumbed the same evening. No autopsy was permitted.

This case exemplifies the utter folly of delay and the great risk in employing the stomach tube. From the conformation of the bone it is very evident that it became fixed in such a way that any manipulation other than esophagoscopy tended to force the bone through the esophageal wall rather than dislodge it. This patient developed in consequence a mediastinitis and possibly a mediastinal abscess to which she succumbed. We regret greatly in not being able to report the postmortem findings.

Case III.—M. G., female, aged six, was referred to us on February 18, 1921, with the following history: seven days previously the child swallowed a button and immediately came to her mother and told her story. For twenty-four hours after the child was unable to swallow solid food, but liquids were taken with some difficulty. Her family physician treated the matter not too seriously and advised waiting a day or two. That he was justified seemed apparent for the inability to swallow gradually subsided and on the fifth day deglutition was practically normal except for a slight pain a moment or two after swallowing. Otherwise the child was perfectly comfortable; she played as usual, slept soundly at night, and seemed to eat normally. The child had been seen by several physicians for the discomfort on swallowing, and they attributed this as due to injury of the throat by the button at the time of its passage downward. The patient had been purged rather vigorously, and the stools were carefully watched but the button had not been recovered. At the time of our examination the child appeared comfortable, and demonstrated that she could swallow water quite normally. Examination of throat and hypopharynx revealed nothing abnormal. Her temperature was 100°, pulse 100, respiration 24.

With such a history we urged röntgenological examination and admission to the hospital. The patient was admitted to the Williamsburg Hospital on February 26, 1923. The x ray immediately told the story as shown by the accompanying photograph. The button was located on a level with the second rib.

Extraction took place February 26, 1923, time two and a half minutes. Under light ether anesthesia the child's size esophageal speculum was introduced and the button brought into view. With a pair of alligator forceps it was firmly grasped and withdrawn. The post esophageal wall was slightly ulcerated and twenty-five per cent argyrol immediately applied. The latter procedure was repeated upon two successive examinations, and the ulceration was seen to heal rapidly. The child made an uneventful recovery, and left the hospital five days later.

The outstanding features in this case are first, the length of time the intruder remained in the esophagus. It was recovered nine days after its inception. Secondly, the absence of any alarming symptoms. After twenty-four hours the child was able to swallow and experienced only slight pain on deglutition.

Case V.—R. S., aged nine years, male, swallowed a fifty cent piece on the morning of July 20, 1923. Immediately after there were no untoward symptoms, there being no dyspnea or interference with respiration. However, the child complained of a heavy feeling in the upper part of the chest. The mother was under the impression that the coin had descended and consequently waited until about noon before she consulted her family physician. At this time the child complained of actual pain in the anterior of his thorax and in the back at the same level. The pain seemed much aggrevated at any attempt to swallow. All foods as well as liquids were regurgitated. It was now that the mother became alarmed and sought her family physician.

The physician seemed rather sceptical because of the size of the coin and treated the matter rather lightly. He ordered a cathartic and assured the mother that the coin would pass out.

However, toward evening the youngster was very uncomfortable and complained bitterly of pain in the chest. Consequently the mother sought another physician the same evening. The latter seemed to recognize the gravity of the situation, and immediately advised an x ray. The accompanying photograph shows the intruder lodged at the cricopharyngeal constriction.

The child was admitted to the Beth Moses Hospital the same evening and under light ether narcosis the coin was quickly removed. The esophageal mucosa was markedly congested and edematous. The child remained in the hospital three days and left on the fourth day discharged as cured.

CONCLUSION

In conclusion, we wish to state that it should be the endeavor of the physician to recognize these cases early and never to underestimate or minimize those symptoms of disordered deglutition when there exists the faintest suspicion that a foreign body has been swallowed. The patient should receive the benefit of at least an x ray before being dismissed. We wish to caution against unscientific procedures and the employment of impliments that long ago should have been relegated to the surgical junk heap. Early recognition and early removal will insure rapid recovery and spare the patient unnecessary pain and suffering, and lastly, avoid those complications to which these patients usually succumb.

Two of the authors' cases omitted will appear in the reprints.

Simplified Transfusion Apparatus*

W. FOREST DUTTON, M.D.,
Philadelphia

FIG. 1.—Funnels adjusted in rubber stopper.

Simplified apparatus in blood transfusion is always desirable, if practical. For this reason the following equipment is described:

A graduated percolator (five hundred c. c.) fitted with rubber stopper; two glass funnels pass through the stopper, one (forty-six mm. with 228 mm. stem) reaching to within two mm. of bottom of bottle, and one (thirty-one mm. with seventy mm. stem) inverted with the glass tube extending above the stopper. The inverted funnel is so inverted in a flanged hole that only about three mm. shows below the bottom of the stopper. Over this is fastened several layers of gauze. A rubber tubing (three mm. in diameter and forty-five to sixty cm. long) with adapter and a sixteen gauge needle completes the outfit. In addition, a Meeker blood letting, or Wassermann, needle may be used conveniently, preventing the repeated use of one needle.

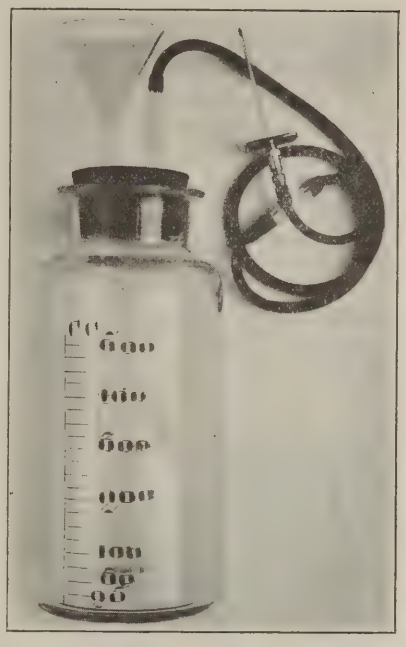

FIG. 2,—Apparatus assembled and ready for use; graduated percolator fitted with rubber stopper and funnels.

When this apparatus is assembled and sterilized, it is ready for use.

For sodium citrate transfusion; five c. c. of the citrate is poured into the intake funnel, and the container turned on its side, revolved several times and then inverted allowing the fluid to flow by gravity through the tubing. It is then placed right side up. The container is agitated gently as the admixture of blood and citrate solution runs into the funnel. When sufficient amount of blood has been secured the needle is removed from the donor and a small pledget of cotton placed lightly in the intake funnel. The citrated blood is now ready to be transported to the recipient. After the venipuncture has been made, the percolator is inverted. Care should be taken to see that the stem of the intake funnel is free of obstruction to inlet of air. The fluid is allowed to flow through the tubing until the air is expelled, then the adapter is attached to needle.

*From the Hospitals of the Graduate School of Medicine, University of Pennsylvania.

ADVANTAGES

1. Simple.
2. Practical.
3. Minimizes chances for infection.
4. Permits of transportation.
5. Filters blood as administered.

A New Retractor for Amputations of the Extremities

E. NEWTON TURKUS, M.D.,
Brooklyn, N. Y.

One feels rather reticent in attempting to add to the already overburdened list of surgical instruments, still another, although in the opinion of its inventor, it may seem quite practical. Fortunately, in the light of modern surgery, so illuminated by the contributions of the immortal Lister, Carrel, Dakin, and others, amputations today are growing less and less, yet, at times, this procedure is indicated and must be met.

It is then, with the intention of simplifying the technic in amputations of both the upper and lower extremities, an awkward procedure at its best, that this retractor was devised.

The flaps being prepared it is our practice to apply the instrument to the soft parts, before paring the periosteum back, thus giving a clear and unobstructed view of the field of operation. The instrument is easily and quickly applied.

It accomplishes the following results:

1. Steadying of the limb by the hands of the assistant passed through the loop handles of the retractor.

2. Thorough retraction of the soft parts, and protecting them from injury by the operator's saw.
3. The services of but one assistant.
4. Dispensing with the use of towels about the soft parts while the saw is in operation, thus preventing the annoyance of having the teeth of the saw catching in their substance.
5. Avoiding injuring the assistant's hands by a sudden manipulation of the saw.

DESCRIPTION OF THE INSTRUMENT

The instrument essentially consists of two cup shaped blades, viz., a male blade, and a female blade both securely riveted to form a sliding joint at the point of attachment. The female blade slides over the male blade, and may be quickly and easily fixed at almost any adjustment desired, to grasp either femur or humerus, depending upon where the operation is being performed. While I originally designed this instrument for amputations of the thigh or upper arm, at times, particularly in large framed or muscular individuals, it is quite handy for lower leg work, and may so be adjusted as to embrace the tibia and fibula simultaneously.

The winged set screw and a stud holds the blades firmly at the adjustment desired by the operator.

The looplike construction of the handles, swinging freely from a roller joint attachment on each blade, is perhaps one of the most valuable assets of the retractor, permitting as is apparent from the accompanying illustrations, the four digits of each hand to slip through each handle, while they and the thumbs steady the extremity, making firm and adequate retraction at the same time (Figs. 1, 2, and 3).

The instrument designed in two sizes meets every requirement for adults. The blades may be of solid construction, or perforated if desired. If perforated, the perforations must be small enough to prevent the muscle fibres from teasing through.

862 Carroll Street.

Tetanus as a Postoperative Complication

ISIDOR KROSS, M.D.,
New York
Adjunct Gynecologist to Mt. Sinai Hospital

A wound received under circumstances where contamination with animal excreta or with soil is either a fact or a possibility immediately suggests the possibility of tetanus. To the average practitioner, tetanus is always associated with an external wound that is infected with animal feces or with soil. The possibility of this dread complication occurring without an external wound, under conditions where contact with soil or with animal excreta can be absolutely ruled out, is usually not entertained until the disease has made such inroads that the patient is practically doomed. Because of the rarity of this complication and because of the failure of early and therefore timely recognition of the disease, I present the following case histories:

Case I.—R. M. was admitted to the first gynecological service (Dr. Joseph Brettauer, director) of the Mount Sinai Hospital, October 4, 1911, with a diagnosis of fibroid uterus. Except for an attack of typhoid fever when she was fifteen years old, the previous history of the patient was negative. On October 6, 1911, there was performed a hysterectomy, bilateral salpingooophorectomy, and appendicectomy. Both the operation and the postoperative course immediately following were uneventful. The first dressing, on October 11th, showed primary healing of the abdominal wound. On the twelfth day following the operation the patient complained of stiffness of the jaw and was found to be rather restless. Examination of her reflexes revealed nothing

abnormal. On the next day, she was unable to open her mouth. The jaws were held rigid and the neck was stiff. The knee jerks on both sides were exaggerated. Babinski reflex was not obtained. Voluntary flexion of the head upon the chest could not be performed. Passive flexion was extremely slight. Rotation of the head was limited but not quite so much as flexion. The jaws could not be separated nor moved from side to side. The upper and lower extremities were perfectly free from rigidity. In the evening there were already present on both sides the Babinski, Oppenheim and Mendel reflexes. The patient was now given one thousand units of tetanus antitoxin intraspinally. At 3 p. m. of the same day there was noted slight twitching of the fingers in both hands. The restlessness had increased and the patient was now complaining of severe headache. At this time (3 p. m.) two thousand units of antitoxin were injected into the neighborhood of the abdominal incision. At 8 p. m. there were administered two thousand units subcutaneously, and at 9 p. m. the patient received an intravenous injection of fifteen hundred units. At 3:30 a. m. of the following day, October 20th, the patient was dyspneic and somewhat cyanotic. Within twelve hours the temperature had risen from normal to 106°. At 9 a. m. the patient was comatose and the temperature had risen to 109°. Shortly afterward she died.

Case II.—W. G. was admitted to the Surgical Service of Dr. Beer at the Mt. Sinai Hospital on November 11, 1912. The patient gave a history of left loin pain three years before admission. Ten months ago, following an injury to the left side, there had developed hematuria for twenty-four hours. Following an automobile accident four days before admission to the hospital, the patient was taken with severe left lumbar pain, and had been passing bloody urine since that time. Physical examination showed marked rigidity on the left side, especially in the upper half, and the presence of a tender mass in the left loin. Cystoscopy revealed the escape of blood from the left ureter. On November 12, a left hydronephrotic kidney, the seat of a marked hemorrhage, was removed. A first dressing, on November 16th, showed that the wound had healed by primary union. Early on November 19th headache and rigidity of the neck developed. This muscular rigidity increased and towards evening involved the muscles of the abdomen and of the back. The patient had difficulty in swallowing and could open his mouth only slightly and with great effort. Knee jerks were increased and the Babinski reaction was present. At 8:35 p. m. he received 1,500 units of tetanus antitoxin subcutaneously. Within the next twelve hours, the muscular rigidity had become more marked and painful spasms developed in practically all the muscles. At 11:50, on the morning of the 20th, 11,500 units of antitoxin were given intravenously. At 9 p. m. of the same day 13,500 units were administered intraspinally. The muscular spasms, however, became more marked and more frequent. The breathing was now labored. At 12 p. m., the patient was stuporous, and was having severe convulsions. On November 21st, at 1 a. m., the patient died, with a temperature of 107° and severe convulsions.

Case III.—F. U. was admitted to the gynecological service (Dr. Joseph Brettauer, director) of the Mount Sinai Hospital, November 27, 1922, with a diagnosis of fibroid uterus and lacerated cervix. With the exception of a mild attack of postpartum sepsis eleven years ago and an attack of influenza three years ago, her previous history was negative. On December 1, 1922, a complete hysterectomy with bilateral salpingooophorectomy and appendicectomy was performed. Six days later, the first dressing was made and it was noted that the abdominal wound had healed by primary union. On the eleventh day after operation a foul purulent vaginal discharge developed, and a pelvic examination revealed the presence of an exudate in the bases of the broad ligaments. On December 15th, just two weeks from the day of operation, it was noted at about 1 p. m. that the patient was unable to open her mouth completely, and that the attempt was painful. Palpation of the parotid regions was moderately painful. No enlargement of the glands, however, could be made out, nor were the lobes of the ears elevated. There was no rigidity of the neck. Examination of the throat revealed nothing abnormal. One hour later there was a slight but distinct rigidity of the neck, and the limitation of motion in the jaw was more marked. No abnormal reflexes could be elicited either in the upper or in the lower extremities. At 4 p. m., three hours after the first abnormal signs had been noticed, the patient was given an intraspinal injection of 15,000 units of tetanus antitoxin. At the same time 8,000 units were administered intramuscularly. On the following day, the rigidity of the neck showed a slight lessening in intensity and the jaws could be opened slightly but distinctly more than twenty-four hours previously. She again received 15,000 units of the tetanus antitoxin intraspinally and 8,000 units intramuscularly. The improvement during the rest of that day continued progressively. On the next day, December 17th, the improvement had become so distinct, that it was decided to withhold further specific treatment. The recovery was complete.

Tenbroeck and Bauer (1), in a study of the intestinal contents of native Chinese, and Tulloch (2) in a similar study with oversea's soldiers, have showed that tetanus bacilli were isolated in normal individuals in 34.7 per cent. and 33.3 per cent., respectively, of their cases. With this as a starting point, the source of infection in the three cases cited above can be quite readily accepted as the intestinal tract and the exciting traumatism as the appendicectomy in two cases, and the intestinal injury (resulting from the automobile accident) in the third. Bearing this in mind, it is rather remarkable to note the extreme rarity with which tetanus is found as a postoperative complication in operations upon the intestinal tract or in injuries involving this tract.

As regards the outcome in the three cases here reported, it seems only proper to call attention, 1, to the very early recognition of the infection, and 2, to the intraspinal administration of very large doses of antitoxin in the third case, and to credit the favorable result to these two factors.

I wish to thank Dr. Brettauer and Dr. Beer for the privilege of reporting these cases.

Practical Therapeutics

DEFICIENCY OF THE HALOGENS IN MODERN DIETETICS*

C. Edgerton Carter, M.D.
Los Angeles, Calif.

INTRODUCTION

Today the importance of what Mendel terms "the little things" in nutrition is being realized as never before. Yet, three quarters of a century ago Chatin appeared before a commission of scientists of the Paris Academy and presented evidence as to the vital relation iodine deficiency and thyroid disorders have to each other. True, Bauman's discovery, in 1895, of iodine in the thyroid gland and Kendall's isolation of thyroxin had not then materialized, to say nothing of the recent strides in biochemistry and the physiology of nutrition.

These reveal a logical interrelation making it possible to grasp and complete deductions that in Chatin's time could have been only conjecture. So in the light of present day knowledge there are many manifestations of iodine deficiency or thyroid gland derangement which may be fundamentally important yet do not come under the group complex of thyroid disease. In fact my contention is that iodine deficiency or halogen imbalance (since bromine and iodine, two members of the halogen group, are both found normally in the thyroid) is at fault in conditions clinically removed from thyroid disease and that disturbed physiological function may arise from deficient iodine intake. This disturbed function, ultimately classified as a disease entity, if detected early may possibly be corrected by the simple expedient of attempting to bring the daily thyroxin output up to normal.

Exactly what normal is and how to ascertain definitely when that norm is reached, are not so simply determined. At the risk of being accused of "looking through iodine spectacles" further introduction will be curtailed. To visualize how vitally the minute quantity of iodine elaborated by the thyroid gland is concerned in its effect upon bodily function and mental activity, we have but to recall that the cretin child is lacking in the ability to assimilate iodine. In laboratory parlance, he is halogen free.

However elusive and infinitesimal some of our essential food elements may be, elucidation of the vitamine group by McCollum has led to an appreciation of the possible abnormal results which may accrue from a continued lack of any basic element in the human physiology, however minute the quantity. When there is a general realization of the necessity for a normal balance of these body activators, and we have learned to apportion correctly the salts and minerals necessary to insure effective physiological function, we shall have made a tremendous stride toward an adjustment of our psychological as well as physiological problems.

Howland and Kramer's results on calcium and phosphorus metabolism, are examples in point. Not only have they shown that these are interdependent in their assimilative function, but that the absorption of both is apparently activated by the synchronous ingestion of codliver oil or some of its elements. Certain basic principles underlying all physiological activity require the fulfillment of their specific conditions before the different organs can function normally. For instance, hypertonic or hyperosmotic solutions, by their effect upon the interchange of body fluids, wield an irresistible and unremitting influence not only upon food absorption, but through the addition of electrolytic ions greater impetus is given to crystalloid diffusion and nerve impulses.

Elimination, a perpetual motion for some seventy years, is constantly aided through kidney activity by means of osmotic pressure in the glomeruli (1), as well as through the excretory function of the epithelium of the tubules. Thus our vital processes are dependent upon, or accelerated by, the various salts and dialyzable substances entering into our daily food. Metabolism itself is activated by normal dilution of the physiological fluids carrying glandular secretions, and nerve impulses facilitated by a favorable reaction of the surrounding menstruum. Therefore the practical question arises, can we check up on these dietetic deficiencies and are there such apparent?

Laboratory tests for the calcium and phosphorus ratio in the blood serum have become routine practice in indicated cases, and we consider no diet adequately balanced unless due weight is given to the mineral intake, the various food combinations and their ease of assimilation. There still remain dietetic deficiencies whose physiological importance are not yet generally recognized but which suggest great possibilities.

This group—the halogens—is comparable to the vitamines in that no known functional test for their isolation has yet been announced, the insufficiency of which sooner or later is productive of functional or organic disability. Like the vitamines, this lack looms large, chiefly because of modern methods of living and of obtaining our food. McCarrison states that in avitaminosis, abnormal conditions arise in the intestinal wall. A further parallel between vitamines and halogens may exist in unsuspected disturbances of the intestinal mucosa by which faulty function originates from halogen deficiency. Certainly hypothyroidism is characterized by the inhibition of normal peristalsis.

Halogens, important dietetically—perhaps chiefly because of the deficiency of their one solid group member—iodine—have an intimate identification with the body fluids, in that they not only may furnish a food directly to the functioning thyroid gland, but also in that they are considered capable of forming electronegative saline compounds which supply nourishing or activating media to the body cells. This physiological principle may be of greater import than we at present recognize and were we cognizant of any practical test for estimating the amount of organic iodine in the circulation at a given time, there could be the same facility in adjustment of this de-

*Read before the Southwestern Pediatric Society, November 7, 1923, and the Los Angeles County Medical Association, April 17, 1924.

ficiency that we now have in the correction of a low hemoglobin. A method recently elaborated by Stieglitz at the Johns Hopkins Hospital, whereby iodides can be specifically identified in the tissue cells, may prove ultimately to be a clinical means for estimating the available thyroxin and thus restoring functional balance (2).

However, our present means of recognizing any such inadequacy as exhibited in a subthyroid condition must depend upon clinical and deductive evidence. As a result, minor symptoms indicative of slight thyroid inactivity may develop gradually without constituting the complete clinical picture, definitely diagnosed as hypothyroidism, and hence are without recognition. Protection against such insidious onset requires sufficient thyroid food to equalize energy demands.

If it is shown that modern methods have made difficult the daily intake of necessary thyroxin precursors, there follows as a logical sequence the possible overwork of the thyroid gland. This results sooner or later in its degeneration and diminished functional activity. No work can be accomplished effectively by the human mechanism without a normally functioning thyroid. To assure this secretory balance of the gland, there are required regular food iodine carriers, which while not comparable in amount to the daily intake of sodium chloride, are comparable in their necessity of being regularly ingested. The normal saline of the blood, for example, constitutes a dilution of some sixty thousand to ten million parts, while the iodine relation is approximately one to ten million or one sixty thousandth as much.

The United States Geological Survey of iodine bearing waters strikingly illustrates the general seaward drainage of the halogen solutions, showing that only sodium chloride has remained in the original bed deposits because of its lesser basic affinity. It is this extreme solubility which accounts for the depleted iodine belts extending north along the Appalachian Mountains into Vermont, thence west through the Great Lake region to Montana, Washington, and to the south including the Rocky Mountains and Pacific States.

According to the United States Army survey, these vast areas are shown definitely to lack in available iodine. In these regions consideration of the required halogen intake must be given and it is highly improbable that man's daily glandular elaborative requirements are here adequately met by the ordinary foods. Conclusions based upon the United States Naval Academy records for 1921 and 1922—in the attempts of Carpenter and Ferguson to stimulate growth by endocrine therapy—state that there is possibly an appreciable percentage of thyropenia throughout the United States.

When we remember that the total storage capacity of the normal thyroid is approximately one quarter to three quarters grain of iodine (3) it is quite possible that our reserve supply is depleted in these days of increased nervous tension much more frequently than we are accustomed to consider. Inhabitants of vast sections in the United States may receive barely one four hundredth as much iodine through their water and food intake as is available to the dweller within more favored localities.

A further deficiency factor lies in the refinement of table salt, producing chiefly sodium chloride, with the total elimination of the remaining halogen group, thus accentuating the handicap to an already depleted glandular system, which originally received replenishment with the daily salt intake and iodine bearing drinking water.

Only when we analyze some of the apparent pathology in the light of its being possibly perverted physiology, do we appreciate the possibilities in a restored halogen balance.

Rabinovitch (5) reporting on epilepsies during the war, says: "There appears to be an anatomical substratum, a proliferation of the subcortical neuroglia in all types. This is present in transitory as well as permanent epilepsy, of Jacksonian, convulsive and psychic types."

Is not this proliferation possibly comparable to the cell edema present in myxedema and other acknowledged manifestations of thyroid insufficiency? And if these phenomena are at all similar in their exhibition, may it not be possible that they spring in part from a common deficiency? Again we have an example demonstrating the intimate association between glandular activity and utilized iodine in Kerr's report from Camp Lewis, Washington (6), regarding the examination of 21,182 men, with the findings of 1,276 goitres, a percentage which corresponds with the natural iodine content found in soil and water in that locality. Furthermore, the United States Government report from the War Department gives a ratio of seventeen to one revealing thyroid glands enlarged, when those dwelling in mountainous districts are compared to the inhabitants of the sea coast regions.

These functionally enlarged thyroid glands may be considered as overworked or underfed.

Statistics accumulated wherever goitre is endemic in widely varying locations throughout the United States, specifically Michigan and Utah—even though both have vast natural sodium chloride deposits—reveal a close association between endemic goitre and iodine distribution.

An interesting corollary to the distribution of iodine by vaporization of sea spray is found in McClendon's report (7). He says that "Rain falling within three miles from the sea coast has one hundred times as much iodine as rain falling a thousand miles removed from the coast." However, it is only one part to the hundred billion at that, and therefore negligible as a contributor of iodine.

The inverse ratio of goitre and available iodine may be much more far reaching in its influence upon health than we at present appreciate. Cretinoid types and pure cretinism, i. e., with no functioning thyroid gland, are known to be frequent in the districts shown by tests to be lowest in iodine content and where by their isolation a fairly definite record of food and atmospheric conditions can be checked.

These suggest a most practical prophylaxis which may be habitually adopted, judging from results secured by Marine and Kimball (8) with their periodical administration of sodium iodide to the goitrous children of the Akron Public Schools. Furthermore, Kimball visualizes the ultimate prevention of cretin, cretinoid and possibly even other glandular imbalances, saying: "The same imagination which de-

veloped the practical application of the principle of the prevention of goitre can now see a few generations hence the closing chapter of endemic goitre and cretinism in every civilized nation of the world." Is it too imaginative to extend these possible results beyond that of mere cretinism and endemic goitre?

Rogers (9) after fifteen years' observation and experiments at the Cornell Laboratories in New York city, recently reports that "All hyperthyroidism has been preceded by a longer or shorter stage of hypothyroidism." If hypothyroidism were recognized before undeniable symptoms were present and before pathological changes had taken place, is it not then logical to expect a resulting decrease in hyperthyroidism, with its classical symptoms and unsatisfactory response at times to any known treatment? Apparently in no way with our present laboratory technic can such a desideratum be attained except by keener clinical observation of the beginning subthyroid manifestations.

Judging from my clinical results during the past two years, it appears quite possible that children exhibiting various symptoms of general debility or nervous instability are receiving an insufficient amount of iodine bearing foods. Furthermore, there is no reason for concluding that this is a condition applying only to children. Constitutional inferiority may be in great measure uncorrected nutritional deficiency—emphatically so, if nutrition in utero is included. Rachitis, congenital and acquired, present many puzzling phases not the least of which is Howland's observation that "Oil from the codliver greatly facilitates calcium absorption." An illuminating angle of the problem may lie in the assimilable iodine percentage of codliver oil, and clinical tests with laboratory checks are now under way with minute doses of iodine substituted for this oil.

Apparently the triad of calcium, plus phosphorus, plus an efficient thyroid, are essential to normal bone development. Normal ossification rate but with rarified bone structure is at times observed clinically to accompany glandular imbalance. Bajon's experiments in Spain upon the rate of fracture repair in rats previously thyroidectomized, disclose such an interrelation (10). Further report of x ray and clinical findings will be made at a later date.

Ralph Pemberton (11) suggests that many forms of neurasthenic headache, migraine and most cases of neuritis, certain types of mental depression and melancholia, and possibly a few supposedly organic conditions are the result of interruption in a chain of metabolic processes. As is generally acknowledged he further says: "A part of the metabolic process is, broadly speaking, oxidative in nature."

Hence, if this hypothesis is tenable, not only is adjustment of the metabolic load indicated, namely, by consideration of diet, elimination, focal infection and rest, but also an increase in cell oxygenation is required. This cell oxygenation is a generally accepted function of the thyroid, and efficient thyroid function is a *sine qua non.*

McCarrison (12) ascribes the need of the thyroid for iodine to various factors, some of which possibly could be anticipated. Excess fats and animal protein, for example, increase the need, while there are further metabolic variations due to childhood, puberty, old age, activity, sex, pregnancy, menstruation, infection, climate and season. These frequently shifting demands upon the thyroid gland cause varying rates of functional activity and naturally make greater or less demand upon the thyroxin elaboration, as well as directly affecting others of the glands.

Possibly thyroxin deficiency resulting from a partially fed thyroid gland extending over a period of years, during which excessive demands were made upon glandular activity, may be ultimately revealed as a factor in the production of abnormal cell proliferation, generically grouped as cancer—particularly cancer originating upon the skin or from the epiblast. It occurs most frequently as follows:

1. In overweight individuals, i. e., those subthyroidizing, according to Duncan Bulkley (13) and Seelye Little (14).

2. In women, especially if living in cities where the nervous tension is increased and where normal physiological needs make possibly greater demands upon the thyroid. It is observed that the cancer rate in cities is higher in women and, according to Little, in both country and city the female rate is higher. One also recalls that Kimball reports that "Girls are six times as susceptible as boys to simple goitre." Hence the iodine reserve of the female is more quickly depleted than that of the male. This is a factor in maintaining resistance not to be ignored.

3. At the time of the menopause, when sexual glands become less active, or whenever glandular balance is disturbed.

4. Possibly in meat eaters, contrasted with vegetarians. This is hardly a fair indictment except as we analyze the effect of foreign proteins with their possible anaphylaxis. These foreign proteins call forth thyroid activity as do all infections. This is perhaps further emphasized by an apparent contradiction reported among the Eskimos, who are meat eaters, yet free from cancer. Their diet, however, of whale and codfish, includes the raw liver, glands and oil, peculiarly active as iodine bearing tissues, and insures the maximum protection possible under a flesh eating régime; this is further protected by a temperature unfavorable to protein putrefaction which lessens the reacting thyroid activity elicited by decomposed protein tissues.

Civilized man's custom of indulging chiefly in protein bearing meats lacking in the protective iodine elements of the Eskimo food, may account for the contention of Duncan Bulkley that "meat constitutes the precancerous diet," but does not prove that a carnivorous diet, if so liberal as regularly to include the halogen group, need constitute a precancerous diet more commonly than the vegetarian. Incompletely split proteins from animal tissue with insufficient iodine for oxidation, may be the dietetic error.

Bearing directly upon this hypothesis, recent investigations by Brown and Pearce of the Rockefeller Institute, show beyond reasonable doubt that apparently the activity of the thyroid—including the adrenals and the thymus—determines the resistance of the individual to the development of neoplasms. Furthermore, in rats experimented upon, where recovery ensued from tumor inoculation and particularly when immunity developed, the activity of these same glands was found to be greater than normal and their evident increased size was retained indefinitely.

(*To be continued*)

Historical Medicine

The Medical Wisdom of O. Henry

LOUIS J. BRAGMAN, M.D.

King's Park, Long Island, N. Y.

INTRODUCTION

O. Henry's father and grandfather were doctors before him, and he, serving an apprenticeship of five years behind the drug counter, was evidently intended for a pharmacist, first cousin to physician. A hacking cough, early developed, sent him off to Texas, and subsequently he became enamored of the wanderlust. Later, as chief diagnostician to the four million and more, he left behind a list of case records, some two hundred and sixty in all, that are unsurpassed to this day.

It was inevitable that his protean pen should touch on the ways of the "disciples of S. Q. Lapius." As he used the cosmos for copy, so did he at times realize the rich veins that lie ever waiting exploitation in the field of medicine.

The following eleven stories are abstracted with a two-fold purpose. The first is to stimulate a direct interest in the original tales, which naturally lose charm and force in the retelling; and the second is to present in a compact form apt and striking gems of medical wit and wisdom gleaned from his thirteen enduring volumes.

LET ME FEEL YOUR PULSE.

(Sixes and Sevens)

The adventures are herein related of one who "came under the spell of the unquiet Lady Neurasthenia." It starts with his examination by a doctor, which for sheer humor is unequalled save by a catalogue of his repast at the sanitarium he first enters: "Phosphoglycerate of lime hash, dogbread, bromoseltzer pancakes, and nux vomica tea."

Fleeing from there because they advocate "absolute rest and exercise," he encounters the consulting physician, who is different from all others, since his uncertainty as to whether he is to be paid or not "insures you either the most careful or the most careless attention."

"No glanders in our family," he volunteers, when requested to trot around the room like a horse for a few minutes. He then proceeds to tie the prescription around his neck because his superstition (all of us have one) runs "to a confidence in amulets."

Of course there is nothing the matter with him, but he is nevertheless extremely ill. He visits a relative in the mountains and after a week grows frightened as he is "sleeping and eating well, and actually beginning to enjoy life." So he visits another doctor, and the "reëstablishing in his mind of the fact that he was hopelessly ill gives him so much satisfaction that he almost becomes gloomy again." For "there is nothing more alarming to a neurasthenic," he admits, "than to feel himself growing well and cheerful."

An old retired country doctor finally tells him that his only salvation is a certain flowering plant, powerfully scarce though it is, and hard to find. "The city doctors," he says, "may know a lot about new scientific things, but they don't know much about the cures that nature carries in her saddlebags." After they both spend a month in the quest of this "cureall plant," he is discharged as recovered into the hands of Amaryllis, girl of his choice, "the name of a genus of flowering plants, and also the name of a country girl in Theocritus and Virgil."

"The formula was true," the old doctor shrewdly said, "even though gropingly at times, the physicians of the walled cities have put their fingers upon the specific medicament."

THE LAST LEAF.

(The Trimmed Lamp.)

"Johnsy," lying in bed with pneumonia, wistfully watches the leaves drop, one by one, from an old gnarled ivy vine on the blank side of a wall visible through the window. The doctor tells her roommate that if she makes up her mind to live, she can bridge the crisis. Despondent and discouraged, she decides to die—when the last leaf falls.

Just before darkness there are four left. In the morning one remains. It holds out vigorously all the day—despite a bitter windstorm. At eventide "Johnsy's" spirit becomes less pessimistic, and she determines to try to get well. The tenacious clinging of the last leaf has taught her the folly of resignation.

She had no way of knowing at that time that Behrman, an artist broken through drink, had painted a leaf on the wall during the night. It was at last the masterpiece he had all his life been striving for, but the undue exposure of the stormy night gave him a pneumonia which terminated his career.

O. Henry reveals the mainspring of therapeutics —the will to get well. "I will do all that science, as far as it may filter through my efforts, can accomplish," says the doctor, "but the way people have of lining up on the side of the undertaker makes the entire pharmacopeia look silly. Whenever my patient begins to count the carriages in her funeral procession I subtract 50 per cent. from the curative power of medicine."

A RAMBLE IN APHASIA.

(Strictly Business)

Bellford was cautioned by his physician against the perils of overwork. "Either your nerves or your brain will give way," he was told. Mention was also made of the increasing frequency, in men of his type, of attacks of sudden lapses of memory.

But busy lawyer that he was, he took heed as busy men do; and one day found himself registered at a New York hotel as Edward Pinkhammer, delegate to the Druggists' National Convention. Forgotten were his home ties, his professional ties, his

Thursday night games of cribbage with his wife, his law books that were his chief recreation. His old fetters stricken from his hands and feet, he discovered anew the glittering Broadway—the street that grows on one "like an opium habit."

Forgotten, too, a sweetheart of his youth, whom he encountered by chance in a restaurant. Forgotten, apparently, her charms, and the romance, and the white roses. Forgotten all, until located at last by a distracted wife and a stolid doctor, his mind came back "as suddenly as it went."

Doubted the sceptic: "Men know about aphasia, and they use it for an excuse." But "why should this man, prosperous, happily married and respected, choose suddenly to abandon everything?" Perhaps because once too routinely his wife flicked "the invisible strand of lint" from his lapel; perhaps because too level were the morning kisses, too inviting the voluminous law books.

Is it true that "the key to liberty is not in the hands of License, but Convention?"

NEXT TO READING MATTER.

(Roads of Destiny)

"Unless they are in the last stages of angina pectoris they are mine in ten minutes after I begin to talk," boasted Judson Tate, gentleman adventurer. He was, by his own admission, as ugly as "A New England Early Christian Scientist," but he stoutly maintained that "handsome is as handsome palavers."

"There are people who spend hours fixing their faces—rubbing in cold cream and massaging the muscles (always towards the eyes) and taking in the slack with tincture of benzoin and electrolyzing moles—to what end? Looking handsome. Oh, what a mistake! It's the larynx that the beauty doctors ought to work on. It's words more than warts, talk more than talcum, palaver more than powder, blarney more than bloom."

Judson knew, for despite his gargoylean features he wooed and won the ravishing Annabela because of his "true lover's eloquence to paint the beauties of his inamorata." Fergus, his rival, though a dead ringer for "Heer Mees," used his charms to no avail, for his protestations of love sounded like "a cheap phonographic reproduction of the ravings of a jelly-fish."

But one day Judson, kin perhaps to Cyrano de Bergerac, injudiciously caught a cold in his laryngeal regions, so that "instead of the usual vibrating words of love and compliment, there came forth a wheeze such as a baby with croup might emit." Annabela, woman that she was, promptly turned to the mute but glorious Fergus.

But not for long. Luckily, a halfbreed Indian druggist was able to restore the defunct vocal organs to their pristine harmony with a potent prescription, and the lady was retrieved, which explains why Judson now walks the street extolling to a hoarse and rasping world the virtues of "Tate's Compound Magic Chuchula Bronchial Lozenges."

How well O. Henry knew the secret of the proprietary quack: "I may as well add," he remarks, "that you can't buy the Chuchula plant in the drug store."

THE DOOR OF UNREST

(Sixes and Sevens)

"There might have been employment here for the alienist or for those who circulate the pledge," when Micob Ader, "wandering Jew that niver was a Jew" related to the new editor how he was condemned to live until the Day of Judgment because he "would not let the poor Christ rest upon the steps."

Actually both were concerned, for once a month, Mike O'Bader, village shoemaker, developed a "rigmarole somethin' about his bein' a Jew pedler." Whiskey was not the cause of, but the recourse from, his periodic hallucination. An errant daughter, whom he had refused to shelter from a crowd that was stoning her out of town a number of years previous, had been found the next day at the bottom of a pond. The parallel that Mike drew was a compensatory atonement for the relief of his harassed mind.

JEFF PETERS AS A PERSONAL MAGNET.

(The Gentle Grafter.)

He was not "a regular preordained disciple of S. Q. Lapius," but he nevertheless could diagnose a street crowd as requiring "a compound hypothetical pneumo-cardiac antiscorbutic tonic," which he himself concocted over the sink with "two dollars' worth of cinchona and a dime's worth of aniline," for each half gross of eight ounce bottles. In selected cases, however, such as the "bad attack of superinflammation of the right clavicle of the harpsicord" the Mayor of Fisher Hill fell victim to, he advocated "a higher power yet, although drugs are high enough." This power he called personal magnetism, "the triumph of mind over sarsaparilla," and it operated by urging that there is "no pain and sickness except what is produced when you ain't feeling well."

He cured the Mayor by making him believe "he could feel the pain he didn't have, leaving," and unblushingly collected a fee of two hundred and fifty dollars. But Jeff, promenading "unillegitimately" as Dr. Waugh-hoo, famous Indian medicine man, was then promptly apprehended by a detective who told the Mayor he was in the employ of the State Medical Society to round up impostors. The Mayor only pretended he was ill to frame Jeff. So Jeff and the detective walked off together, and divided the two-fifty between them, for they were pals in arms to put one over on the Mayor, which they sklilfully did thanks to "the great doctrine of psychicfinanciering." Jeff had a succinct philosophy on the profession of "gentle grafting." He peddled medicine on the street to the poor, but would not practice personal magnetism on them. "I do not drag it in the dust," he explained, "because they haven't got the dust."

AT ARMS WITH MORPHEUS.

(Sixes and Sevens.)

Tom Hopkins, feeling blue and shivery, "mistook the morphine bottle for the quinine, and in about eight minutes sank back into a gentle collapse." His host sent for a doctor who gave him "citrate of caffeine in frequent doses and strong coffee," and

ordered him walked up and down the floor so that he might be kept awake.

The somnolent power of the drug was overwhelming, and it was imperative that, since his body could not be aroused, his mind should be kept alert. It occurred to his friend that the most efficient way of stimulating his thoughts was to invoke his anger. Creating therefore what he believed to be a fictitious situation, he scornfully accused Tom of behaving like a scoundrel and a cad in casting aside his sweetheart at home now that he had attained wealth and position in the city.

The ruse worked. Tom, becoming hostile and resentful, was sufficiently aggravated by the accusation to tide over the hour of imminent lethargy. The situation, far from being unreal, however, actually existed. The next day, his senses cleared, Tom felt the sting of conscience and sent for his neglected girl. Anger has its uses—regardless of the after effects.

THE MARIONETTES.

(Rolling Stones.)

It is difficult to conceive of "medicine—and burglary wedded"! Charles Spencer James, M.D., was just as apt in treating fractures as in fracturing safes; whether on the "case" or the "job" he maintained a strict business attitude. In fact, such was his "manner of poise, of sureness, of ability to overcome fate" that "at his first professional visit, women would tell him where they hid their diamonds at night from the burglars."

Late one evening while returning from a "job" with his "immaculate medicine case" that served as "a voucher for his honesty of person and purpose," and which actually contained a set of tools used by the up to date safeblower, he was summoned by chance to the bedside of a dying man. Putting his ear to the heart to verify his diagnosis of mitral insufficiency, he caught the whispered words: "Tell her—the twenty thousand dollars—her money."

The doctor—or the burglar? For a moment the two clashed—then decided to harmonize. If the secret could be extracted from the lips of the dying man. . . . But there was no time to lose. "The pulse under his fingers was as fine and small as a silk thread." Unhesitatingly he took from his bag a four-ounce vial of nitroglycerine, half of which had two hours earlier been injected into a hole drilled in the lock of a safe. Diluting it "one drop with nearly half a tumbler of water" he now had a solution of glonoin, the most powerful heart stimulant known to medical science," one fiftieth of a minim of which he was to use "to shiver the prime machinery of a human being."

For he knew that "over stimulation in this form of heart disease meant death," inasmuch as "when the clogged arteries should suffer congestion from the increased flow of blood pumped into them by the power of the burglar's 'oil,' they would rapidly become 'no thoroughfare,' and the fountain of life would cease to flow." A few minutes after injecting the solution "into the muscles of the region over the heart," the pulse began "beating in great throbs, with ominous intervals between."

Temporarily arousing his victim's brain cells, he learned to his dismay no revelation of secreted wealth, but the story of the squandering of a wife's fortune at the racetrack by a reckless spendthrift.

The doctor was a bit too anxious. A glimmer of understanding came to the dying man ere his heart failed him utterly. "Doctor and safeblower," he muttered. "Do you—make—the—combination—pay?"

HYGEIA AT THE SOLITO.

(Heart of the West.)

Cricket McGuire, expugilist and allround sport, was stranded in San Antonio after losing his pile in a bout across the river. "A nickel and gallopin' consumption" were his residuals; "a croaker" had given him six months to live.

Raidler, of the broadhearted breed of ranchmen, saw him "torn by a spasm of that hollow, racking cough," and from sheer compassion took him home to the Solito, where "the air was wine and seltzer." But Cricket, chronic grunter, scorned the gifts of Nature, and whiled away the precious days in "a vilely close room," smoking himself to death in the chair of indolence.

Inevitably he was taken for a malingerer, since his physical appearance was inconsistent with the advanced stage of the disease. The doctor, coming to the ranch on a chance visit, examined the wrong man, and reported erroneously that Cricket had the "lungs of a burro and the constitution of a steer."

So they thrust him out with the cowpunchers as punishment for his pretensions. But goaded into vigorous anger at being stigmatized as an impostor, he hurled himself to work with a vengeance, and a "hem'ridge" was the consequence. Ever ready to forgive, his remorseful associates nursed him back to health and vigor by feeding him "chopped raw meat and whiskey" and keeping him close to the ground, "where the medicine in the air stays."

There is no intention here to introduce a new therapy. But had Cricket not been thrust out of his indifferent submission to fate and cast into an environment where his recovery was a matter of vindication, he might never again have been able to demonstrate his famous "shore perplexus punch."

MAKES THE WHOLE WORLD KIN.

(Sixes and Sevens.)

This is a tale of kindred souls—sufferers from inflammatory rheumatism. A burglar, ordering a man in bed to throw up his hands is told it cannot be done because of an affliction of the shoulder. For years himself a martyr to rheumatism, the burglar develops a fraternal feeling for his victim, confessing that he himself was compelled to renounce secondstory work because he frequently would get stuck halfway up with a deadly twinge.

The two then begin to swap stories of remedies tried—and found wanting. They mutually condemn rattlesnake oil, Pott's Pain Pulverizer, Blickerstaff's Blood Builder, and opodeldoc, which latter they agree is a "salve suitable for little Minnie when the kittie scratches her finger."

Both are dead certain, however, of the efficiency of "a little old sanitary, lest we forget Booze," and arm in arm the erstwhile burglar and the quondam victim march off to re-affirm its reliability. It was the little touch of rheumatism that saved the day.

A FOG IN SANTONE.

(Rolling Stones.)

"There are some whom, when the terrible god Phthisis wishes to destroy he first makes beautiful." Such was Goodall, hibernating in Santone with the Three Thousand other "wooers of the ozone." But the town, which had the "purest atmosphere, sir, on earth," was one day unprecedently smitten with a cold gray fog, and "the tubercles, whose ravages hope holds in check, multiplied." As a consequence "on the red stream of Hemorrhagia a few souls drifted away"; others, having reached the tether of despair, used "whatever came handy to their relief, pistol, gas or the beneficent muriate."

Goodall elected morphine. Thirty-six grains had he succeeded in purchasing. On the verge of using them, he was sidetracked temporarily by a "seeker after Nepenthe," whose doctor had given him four weeks and who had been "vaccinated with whiskey and codliver oil." Together they sought consolation in the bottle. But to no avail; it only made him "disremember to forget."

Later in the evening found him in a restaurant, unburdening his soul to a woman of "Evelike comeliness." Her he told how he journeyed South for the climate "to escape the hereditary foe of his family"; how according to a specialist his calendar contained but a few more leaves; how in anguish at his failure to get better he had stocked up on morphine. The woman, mother-confessor and consoler, pleaded the cause of hope. "A tonic day," she inspired, "will dawn sweet and prosperous."

Goodall left her buoyantly, with renewed spirit. And the woman herself? We are not told just why she poured the morphine he left behind into her beer and casually drank it down.

Contributors to the Science of Medicine

JOHN WESLEY, JEAN PAUL MARAT, JAMES GRAHAM

W. J. Turrell (*Annals of Medical History*, December, 1921) states that it would be difficult to find three men differing more widely in character and temperament than the "eminent divine and credulous enthusiast . . . the revolutionist and scientist . . . and the fanatical quack." Wesley lived from 1703 to 1791. He did not begin practising medicine until he was forty-three, when he opened a dispensary at the Foundery, Moorfields, London. He took this step in an attempt to remedy the condition of the poor whom he encountered in his preaching. "I will prepare and give them physic myself," he decided. In spite of opposition on the part of the medical profession, the dispensary seems to have been a success, for he opened another at Bristol within two months. In the following year, he published his first medical work, *Primitive Physic*, or an *Easy and Natural Method of Curing Most Diseases*. This book attacked the qualified physicians of the time, and was of course severely criticized. But its success among the poor was so great that it reached twenty-three editions during Wesley's lifetime. In 1758 he published *Advices with Respect to Health, Extracted from a Late Author*. The late author was Doctor Tissot. This book is especially interesting as containing the first reference to electrical treatment to be found in any of Wesley's works. He made the claim that "electrifying" cures all kinds of sprains. Nearly twenty years later he brought out anonymously his remarkable work, *The Desideratum*, or *Electricity Made Plain and Useful; by a Lover of Mankind and Common Sense*.

Probably Wesley got his first information about electrical treatment from the works of Richard Lovett, a lay clerk at Worcester Cathedral. Lovett recommended treating many diseases in this way, among them, St. Anthony's Fire, bronchocele, epilepsy, gout, headache, palsy, rheumatism, sciatica, sore throat, and fistula lachrymalis. His treatment of hysteria and similar ailments seems to have been most thorough. Wesley in *The Desideratum* follows closely Lovett's practice. "The most remarkable feature of his own book is the fervor with which he appeals for a trial of the curative effects of electricity."

The instruments available for electrotherapy at that time were the frictional machine for the generation of static electricity, and the Leyden jar, discovered by Von Kleist, dean of Camin Cathedral. Three methods were apparently in use: 1, Sitting on the electrical stool or resin, corresponding to the present method of static charge or bath; 2, drawing off sparks from a person so charged, the static sparks of today; applying sparks to a patient from a charged Leyden jar. The alleged cures making up most of Wesley's book are for the most part absurd and unreliable. Although both Lovett and Wesley were unqualified practitioners, their genuine belief in the curative properties of electricity and their enthusiasm did a great deal for the early development of the science, of which they were the first English practitioners. Priestly, in his valuable *History of Electricity*, recognizes this fact. He writes: "If in such unskilful hands it produced so much good, and so little harm, how much more good, and how much less harm would it possibly have produced in more skilful hands?"

Jean Paul Marat, scientist, revolutionist, oculist, pulmonary specialist and electrotherapist, lived from 1743 to 1793. He spent ten years in London practising. He wrote a friend that he came to London to educate himself in science and to avoid the dangers of dissipation. In 1775 he was admitted to the degree of M.D. St. Andrews. His first work on the subject in question was a pamphlet, *Discov-*

eries on Electricity. In 1784, his book, *Mémoires sur l'Electricité Médicale,* appeared. In this he repudiated many of the absurd and extravagant claims of his predecessors and contemporaries. He claimed to show definitely in what diseases electricity is of value, determined the method of its administration, and defined the efficacy of its actions, and, to some extent, he justified his claims, for his work was certainly on far more scientific lines than the writings of his predecessors, or even of many of his successors. He considered electrical treatment justified in cases of external indolent tumor, edematous engorgement of the limbs, cutaneous eruptions, paralysis, hemiplegia, rheumatism, sciatica, and painters', enamellers', and founders' colic. He insisted upon fixing definitely the duration of treatment, that there must be fixed doses of electricity as well as of other medicines. A séance should last twenty minutes or more, and should be repeated three or four times a day. Strong shocks are prohibited. Weak shocks should be used at first and gradually increased in strength. All of Marat's writings reveal an overwhelming selfconceit, and the obsession that everyone was against him—characteristics, combined with his unusual ability, that led to the development of the extreme, revengeful and bloodthirsty revolutionist he afterwards became.

James Graham (1745-1794), of Edinburgh, is perhaps not so well known as Wesley and Marat. He "affords a striking example of an electrical quack, a class which still flourishes in this country, tolerated by an indifferent or indulgent government, and largely patronized by a gullible public." He was the son of a saddler of Edinburgh, and is said to have studied medicine at the university, but it is doubtful whether he ever took a degree. He practised as an aurist and oculist in America, and may have acquired some knowledge of electricity from the works of Benjamin Franklin, but it is certain that he imbibed none of his quackery in this way, for Franklin was most skeptical as to the advantages of electrotherapeutics, as his writings show. Graham soon returned to England and practised electrical treatment at Bath, Bristol, and London. One of his patients was the Duchess of Devonshire, and her patronage proved a stepping stone to fame and fortune, for he soon established himself at the Temple of Health, Adelphi House, London. His establishment was fitted up with the most ornate and elaborate electrical equipment, including an electrical throne, insulated upon glass pillars. He asserted that he spent ten thousand pounds on the installation. Even this did not satisfy his ambitions, for he soon opened the Temple of Health and Hymen at Schomberg House, Pall Mall. Here he won most of his fame by becoming associated with the notorious Emma Lyon, afterwards Lady Hamilton, the companion of Nelson. Graham is supposed to have used "frail Emma" as the Goddess of Beauty and as a model for his lectures on health. Horace Walpole wrote in his Letters that Graham had "the most impudent puppet show I ever saw, and the mountebank himself the dullest of his profession, except that he makes the spectators pay a crown apiece." Southey calls him "half enthusiast, half knave."

Graham's method of treatment consisted of placing patients in baths or on the "magnetic" throne; his specialty was the treatment of sterility, the cure being effected through sleeping in the "celestial bed" at fifty pounds a treatment. He was an early exponent of the virtue of mud baths, sometimes burying himself for hours at a time in the earth. He decried the eating of flesh and alcoholic excess, and advocated cold baths, ventilation, and sleeping on hard mattresses. He claimed that all diseases were caused by wearing too many clothes. Towards the end of his career he suffered from religious mania and had to be confined to his home.

It is no wonder that the science of electrotherapeutics, sponsored by such godparents, passed throughout a troubled and neglected childhood.

Two other names stand out prominently in the development of electrical treatment because of their valuable contributions to the science—Duchenne of Boulogne, famous in neuropathology, and Dr. Golding Bird, who established an electrical department in Guy's Hospital, and in 1847 gave a course of lectures before the Royal College of Physicians on electricity and galvanism in relation to physiology and therapeutics.

PRESERVATION OF THE LISTER WARD.

During the past several months, the question has come up in Great Britain of the destruction, for various published reasons, of the famous ward in the Royal Infirmary of Glasgow where Lister worked out the principles of antisepsis. This proposed step has raised a storm of protest, not only from many members of the medical profession, but also from men and women who believe that the ward should be retained for historical and civic reasons as a monument to a man who knew neither class nor creed, but adopted humanity itself as a field for his work. Other nations have done honor to Lister in their public monuments, as, for instance, France, who, during the Pasteur centenary celebration, unveiled a marble panel in the Sorbonne commemorating the spot where Pasteur and Lister once embraced.

Pasteur and Lister have been called the fathers of modern surgery, the former because he developed and reduced the theory of microbes into a science, and the latter because he applied the theory to practical ends. Lister was the child of Quaker parents and retained throughout his lifetime much of that simple faith and its fruit, the love of mankind. The controversy over the Glasgow ward brings to mind the occasion when Lister's discoveries first excited popular interest. This was when Sir William Jenner, physician to Queen Victoria, sent for Lister for assistance in treating an alarming condition in the Queen contigent upon an abscess. Making use of his newly discovered methods preventive of blood poisoning, Lister performed a successful operation. However, although there was immediate relief, pain and fever recurred. Lister came to the conclusion that these were due to insufficient drainage of the abscess, and so strong was his faith in his antiseptic principles that he made his first experiment upon a queen—and with success. From that time on his fame was assured.

THE THERAPEUTIC VIRTUES OF BRIMSTONE AND TREACLE

Mr. Wackford Squeers, the Yorkshire schoolmaster in *Nicholas Nickleby* and one of Dickens's immortal characters, has undergone recently somewhat of a whitewashing at the hands of one of the most celebrated of British surgeons. Sir Arbuthnot Lane, speaking at the annual meeting of the Invalid Children's Aid Association, declared that Mr. Squeers, whom Dickens stigmatized as the type of the cruel, ignorant and mean schoolmaster who infested certain districts of England at the time in which he wrote, was so far as the early morning diet of the scholars was concerned a benefactor to the youths under his charge. Sir Arbuthnot Lane pointed out that probably the greatly pitied pupils of Dotheboys Hall really owed long and happy lives to their morning dose of brimstone and treacle, both of which are ideal foods and beneficial to health in a high degree.

No doubt the London surgeon intended to drive home the point that the sophisticated and largely artificial diet of civilization is not conducive to good digestion and good health. He drew attention to the fact that coarse treacle is a better food than highly refined white sugar and that whole meal bread is more nutritious and beneficial to health than white bread made from closely milled flour. Sophisticated food in any form from which the vitamins have been wholly or partially removed is not so invigorating as the more primitive foods in which the vitamins have been left. The reason for this is ridiculously simple, because vitamins are essential to good health. Again the coarse foods are better not only because they contain the vitamins and certain necessary salts, but for the reasons that they provide masticating exercise for the jaws and teeth, keeping the teeth in good condition and they also, because of their coarseness and roughness, encourage peristalsis and are means of overcoming constipation, one of the greatest banes of civilized life.

The soft pappy food and candy and other sweets which are consumed in such large quantities nowadays are fruitful causes of constipation and of bad teeth. Therefore it is true to some extent that the Spartan diet prescribed by Mr. Wackford Squeers and his even more formidable Amazonian helpmeet was beneficial to the health and good for the complexion. Mr. Squeers, although Dickens did not intend that his writing should be so interpreted, was, in fact, cruel only to be kind, as it is undoubtedly true that a luxurious diet, the diet of present day prosperous civilization, is not nearly so valuable physically and mentally as the simple coarse diet of a primitive people. Moreover, many chronic diseases can be long kept at bay by careful attention to food and habits of life.

THE CLINICAL VALUE OF BASAL METABOLISM.

The estimate of the basal metabolism, that is to say, the minimum amount of heat produced by the organism in repose, fasting and in a normal temperature, calculated by square metres of cutaneous surface and by the hour, is a procedure which of late has passed from the laboratory to current clinical practice. Although the technic is not so simple or rapid as taking the temperature or blood pressure, one can, nevertheless, utilize this method for the diagnosis of certain pathological states in which it will give very important data. With Boothby, the following divisions may be accepted; diseases with a normal basal metabolism (-10 and $+10 \times 100$); diseases with a high basal metabolism (below -10×100).

But Maranon and Carrasco, who have studied this subject very carefully, say that as yet one must not make the conception of metabolic rapidity a conception of general pathology. It is to be confined to the pathology of the organs of internal secretion, especially the thyroid. This opinion bears weight as it is based on 177 cases.

In hyperthyroidism the metabolic rapidity is always increased so that any high metabolic figure should cause one to think of the various forms of this affection. The degree of hypermetabolism will indicate the intensity of thyroid hyperfunction, but it does not quite indicate the gravity of the disease which also depends upon other factors. The prognostic value of metabolic data is therefore relative.

The estimate of basal metabolism is of great value for the differential diagnosis between the atypical forms of hyperthyroidism and the complex disturbances met with in certain subjects—neuropathic, neurasthenic, or hysterical—with manifestations, principally vegetative, such as tachycardia, palpitations, subjective cardiac sensations, distress, tremor, and violent vasomotor reactions. However, in some of these clinically doubtful states, metabolism gives doubtful results.

Hypothyroidism gives a low basal metabolism so intense, in fact, that a low figure always indicates thyroid insufficiency, even when the clinical symptoms of hypothyroidism are doubtful.

The genital glands act on metabolism in the same way as the thyroid and for this reason in pure cases of genital insufficiency — especially ovarian — the metabolic rapidity is decreased. When ovarian insufficiency is combined with thyroid insufficiency, the hypermetabolic action of hyperthyroidism predominates; hence the estimate of the metabolism is not of much use for the diagnosis of genital changes.

The hypophysis acts like the thyroid, hence in acromegalia, the metabolic figure is rather high, sometimes very high. If this affection is, as is frequently the case, combined with thyroid insufficiency, the hypometabolic action of the latter predominates. In the sure or doubtful clinical types of pituitary insufficiency, Frölich's syndrome, infantile adiposis, pituitary cachexia and prepuberal pseudohemaphroidism, the metabolism is rather low. In obesity, the basal metabolism depends upon the hypoglandular disturbances so frequent and important in its pathogenesis, hence its estimate is important for controlling thyroid medication.

Although Maranon and Carrasco have never noted hypometabolism in Addison's disease, they suspect that the suprarenal gland exercises a rapid and energetic, although fleeting, action on metabolic rapidity, but as yet no diagnostic value can be attributed to it in affections of the suprarenals. The basal metabolism and its pathological variations depend upon the internal secretions and its estimate offers an excellent method for diagnosis and control of treatment.

DISEASES OF ANIMALS

It has recently become evident that in the study of human diseases that of the diseases of animals may be extremely useful. Comparative pathology may aid greatly in throwing light on points that have long puzzled medical investigators. Animals are subject to many of the diseases to which men are subject and, in short, investigations in this direction open up a wide field and should yield valuable results. Little has been done hitherto along these lines even in the case of domestic animals. At a meeting of the Section of Comparative Medicine held in London on March 26th last, a discussion was held on the comparative pathology of captive animals and man. Dr. N. S. Lucas read a paper and pointed out that the subject was much wider than a comparison of such diseases as tuberculosis, glanders, anthrax in man and animals, or in the relation of smallpox or ordinary cowpox. The study of this comparative pathology had been poorly developed, because so far as he knew, the Zoological Gardens in New York and London were the only ones in which postmortem examinations on the animals which died were systematically carried out and the results recorded. The study was further hampered by the dearth of knowledge concerning wild animals in their normal state. Of course, it is obvious that captivity has a very considerable influence on the lives of animals, in some respects shortening life and in many instances lengthening it. Animals in the zoological gardens were free from many diseases which afflict mankind and even domestic animals resulting from work or the strain of overstimulated reproduction.

The speaker might have said that animals kept in captivity under scientific supervision did not suffer from the diseases of civilization largely due to faulty diet, from which man suffered and from which domestic animals were likely to be afflicted to a less extent. But animals in captivity were prone to some diseases which did not attack human beings although, on the other hand, many human diseases were unknown in captive animals. Acute specifics, including syphilis and gonorrhea, were absent. Acute rheumatism and endocarditis were very rarely met with, although he had seen a severe case in a monkey.

As for malignant disease, which is increasing so rapidly among civilized people that many are now classing it as a disease of civilization, Dr. Lucas said it was moderately rare in these animals, but not because the animals were too young for that disease to manifest itself. Carcinoma of the thyroid was fairly frequent in dogs, and in the zoological gardens, wolves, jackals and wild dogs had been affected with it. Melanotic sarcoma of the suprarenal occurred in the antelope, and sarcoma of the palate had been detected in an ostrich, and when death eventually ensued there was a secondary growth in the intestine. There had been no case of sarcoma or carcinoma among the apes or monkeys for twenty years.

Professor G. H. Woolridge, a veterinarian, said that most of the cases of tuberculosis in the zoological gardens had been found to be due to the bovine strain of the bacillus. There was no doubt about the feeble resistance to lung conditions in these animals, and the bad results were aggravated by the fact that the patients had no power to communicate that they were ill until the disease was very far advanced. The comparative absence of malignant disease in wild animals in captivity was a matter for comment as many of the denizens of the zoological gardens had lived beyond the age at which domesticated animals developed cancer.

Mr. M. T. Rowlands said he had been informed that the pig was the only animal which could be infected with aviary tuberculosis and he thought therefore that the latter could also infect human beings. By giving his pigs runs in a wood and feeding them on foods with a vitamin A content he had abolished tuberculosis from one farm entirely. The study of comparative pathology is yet in its infancy and it will

be many years before it is placed on a firm basis. However, the ground is unexplored and it is probable that many discoveries will be made of great service to the human race. While there is little analogy between the conditions of life of domesticated animals and those in captivity in zoological gardens, certainly not sufficient to attempt to build theories, yet it is open to speculation whether the more or less civilized life of domestic animals and especially their diet has any bearing on the fairly common occurrence of cancer in domestic animals and its rarity among anivals in the London zoological gardens. Does civilized life account for the more or less frequent occurrence of cancer among domestic animals as it is claimed to account for the great and increasing prevalence of cancer among civilized beings in contradistinction to people living under primitive or simple conditions.

THE PARATHYROID GLANDS.

Careful investigations have unveiled a great many of the obscure points with respect to the endocrine glands and other as yet not understood features are in the process of being cleared up. But there remains much to be elucidated in connection with the physiology of these organs. The functions of the parathyroid glands, for instance, are by no means thoroughly understood, indeed little concerning their physiology is really known. Therefore any addition to our knowledge of the subject is welcome.

In the *Lancet,* March 31, 1923, is a brief review of some observations made on the parathyroid glands by Harald A. Salvesen, of the Physiological Institute of the University of Christiania, contributed to the *Proceedings of the Society for Experimental Biology and Medicine,* Vol. xx, No. 4, 1923. It is pointed out that of the many theories as to their functions, only three have gained importance, viz., that the parathyroids control, 1, the guanidine metabolism, and so regulate the tonus of muscles; 2, the calcium metabolism and 3, the acid base equilibrium, their removal causing alkalosis. They are also supposed to contain the sugar metabolism to some extent, a supposition which is held regarding the other ductless glands. Salvesen's experiments were made with dogs. After partial and complete parathyroidectomy had been performed he studied the changes in certain constituents of their blood, care being taken to leave enough thyroid tissue to prevent cachexia. The results of these experiments were to demonstrate that when there is a fall in the calcium content of the blood there is parathyroid insufficiency. In fact the most marked characteristic of this insufficiency is the fall of the blood calcium, which fall is in proportion to the amount of parathyroid tissue removed.

It has been suggested, previously, that a province, if not the province, of the parathyroid glands is to fix the calcium content of the body. The outcome of Salvesen's experiments tend to verify these suggestions. If, then, the parathyroids do control calcium metabolism, and so it certainly appears, they further influence the functions not only of the muscle and nerve tissue, but probably of all the organs. Accordingly the functions of the somewhat despised parathyroids, despised because they were not understood, seem to be of the first importance. And this raises the hope that a thorough knowledge of the ductless glands, and of the means to keep them in smooth working order, will perhaps revolutionize the practice of medicine.

First, the thyroid has been shown and now the parathyroids have been shown to be essential to the proper working of the human economy. Moreover, although each ductless gland has its peculiar function or functions, they are interdependent. Hurst, Vines and others investigating the same field have given clinical demonstration that the parathyroids influence the blood calcium and that the removal of the parathyroids lays the nervous system open to attack. Salvesen has experimentally confirmed these findings that with the removal of the parathyroids, the threshold for the excretion of calcium is lowered. While it is true, as Sajous has recently taken occasion to point out repeatedly, our exact knowledge of the physiology of the ductless glands is even now singularly limited, we are steadily but surely accumulating facts in this direction and in the course of time shall reach the goal. No road leading to health promises so much.

THE HEALTH ADMINISTRATOR AND THE CANCER PROBLEM

"A problem that has increasingly weighed upon my mind in recent years is the problem of what health departments ought to be doing about cancer," writes Dr. Eugene R. Kelley, State Commissioner of Health, Boston, in a significant article published in the July issue of the *American Journal of Public Health.* Dr. Kelley discusses the problem of cancer and the health administrator from many angles and in detail. He feels, in common with many other members of the medical profession, that this fast increasing disease is a huge public health problem, ranking perhaps with mental disease, and as a racial menace far outstripping tuberculosis, venereal disease, infant mortality, and industrial stress and strain. He urges that the American Public Health Association and other bodies and organizations

struggling with the cancer problem make an effort to formulate collectively a practical program of continent wide activity in this field on the part of health departments, and a campaign that will be of practical lifesaving value not disproportionate to the amount of attention and money necessary to the successful operation of this program. The main lines of attack should be, considering that cancer is not a purely medical but also a social and humanitarian problem: 1, studies and research on the etiology of cancer; 2, studies of facts relative to past prevalence and curability, with all possible statistical data arranged and tabulated to afford a basis for a comprehensive followup; 3, adequate provision for early differential diagnosis after the case is in the hands of the physician; 4, adequate hospitalization where it is needed, both in operable and nonoperable stages of the disease; 5, an effective educational campaign. Dr. Kelley believes that the facts on cancer are sufficiently menacing to call for the active cooperation of everyone "to fight this enemy of human existence to a finish and to enlist every bit of human experience and knowledge in the struggle instead of waiting in fatalistic indifference for someone, somehow, somewhere, sometime to solve the riddle and cage the monster."

DRUG ADDICTION

If one is working at a thing he will either see it calmly or in a highly exaggerated light, according as he is of a scientific or a sentimental mind. Possibly in the former mental state one may give the subject less consideration than it deserves, but he is more likely to be on the side of fact.

Kolb and Mez of the Public Health Service have just issued a report on the subject of the Prevalence and Trend of Drug Addiction in the United States, and at the same time the International Narcotic Education Association has been putting out special literature along the same line.

The former believe that "While it is impossible at the present time to make an exact count of the persons addicted to narcotics in the United States, in an individual State, or even in one of our larger cities, because of the social and legal factors tending to make addiction a secret practice," the public health servants believe "that it is possible, by utilizing all of the information now available, to delimit the number of certain maximum and minimum figures."

The data from six independent surveys, made in different parts of the country, are strikingly similar so that the estimates made from them for the entire country can hardly be far wrong. In summarizing their analysis of these statistics they say "The evidence seems to show that a maximum estimate for the number of addicts in the United States at the present time would be 150,000. The estimates based on actual counts and on the available supplies of narcotics, together with the conditions reported by the physicians interviewed, point to about 110,000, which number is believed to be nearly correct. The number of addicts has decreased steadily since 1900. Before this decrease set in there may have been 264,000 addicts in this country. The quantities of narcotics imported by this country at the present time are believed to be only slightly in excess of the amounts required to supply medical needs. While physicians have been credited with being responsible for the creation of many addicts in the past, it is concluded that but few cases of recent addiction can be so attributed."

On the other hand, The International Narcotic Educational Association believes that heroin addiction, especially by children, is growing by leaps and bounds. "Many authorities agree that the average addict is twenty-two years of age and that each new addict starts recruiting others." "It is the custom to give away heroin free to youth until he or she is hooked." They report "snow parties" and warn against "using any brand of face powder regularly unless it bears the name of a reputable maker or has been analyzed for the drug." "In the case of the average heroin addict, still in his minority, six doses produces an addict." "The great expansion of narcotic addiction in America dates from 1910. The expansion continues almost unchecked, in spite of legal restraint and efforts at salvage of victims." The association has made no survey of the situation.

We can take our choice between the report of the above investigations carried on in different sections of the country and by different agencies, and the statements of the International Association which is certainly greatly interested in the subject.

BETTER LATE THAN NEVER

"Seeing as how" we have come to have national prohibition, a cure for alcoholic intoxication comes rather late in the day. However, it may still be of not infrequent use. This cure is the unexpected outcome of work in physiology which was begun only a quarter of a century since, and which has probably resulted in more practical benefit than any other purely physiological research ever conducted.

Carbon dioxide has long been considered one of the most useless, if not poisonous, substances produced in the animal body, and we believe it was Professor Yandell Henderson who first pointed out that, if it was a deleterious thing, the body kept on hand an astonishingly large amount of it, since there is, at all times, twice as much in the blood as

there is of oxygen. While, like sugar, or salt or even water, it is evidently a poison when it accumulates in excess, there would seem to be some good use for the large amount kept in circulation. The hormone properties of the compound came into view, and, at one time, a likely theory of surgical shock grew out of this idea.

It has been known, of course, for some time that carbon dioxide is the delicate regulator of respiratory frequency and depth, acting thus to control nicely its amount in the blood. By preventing its normal escape from the lungs, as by increasing the amount in the inspired air, and thus partially damming it back in the blood, the respirations are increased in depth and frequency, Henderson happily hit upon this procedure for aiding nature in getting rid of carbon monoxide in poisoning from this gas. By supplying to the victim a mixture of oxygen and carbon dioxide, the oxygen, through the respiratory stimulation of the carbon dioxide, is much more rapidly taken up and the carbon monoxide replaced. From the curative viewpoint this is one of the most brilliant direct applications of physiology.

Following a suggestion of Henderson, Hunter and Mudd have applied this method of carbon dioxide inspiration for saving or sobering cases of alcoholic intoxication. The experiments along this line which they describe in the *Boston Medical and Surgical Journal* of June 5, 1924, have been carried out clinically as well as in the laboratory. In four cases of alcoholic coma there was rapid revival. None of the cases had, on the following day, the usual leftover symptoms—headache and nausea. The deeper the coma, the more marked the improvement.

It is suggested that in cases of methyl alcohol poisoning "carbon dioxide would be even more efficacious, as, due to its lower boiling point, it has a higher partial pressure than ethyl alcohol, both being at the same concentration."

Obituary.

ADELBERT A. GETMAN, M.D.

Dr. Adelbert A. Getman, a life long resident of the village of Chaumont, N. Y., and one of the oldest practicing physicians in northern New York state, died suddenly at his home on July 26th, from heart trouble. Dr. Getman was born in 1851, and attended the Albany Medical School, his internship being served at Park Hospital, New York. He became interested in the lore of the American Indian, and gathered together a large collection of relics and fossils. Parts of his collection were given to the New York Museum of the American Indian in New York, to the educational department at Albany, and to the Smithsonian Institute.

JOSEPH R. BROOME, M.D.

Dr. Joseph R. Broome, president of J. R. Broome and W. F. Brainard, Incorporated, publishers of medical books, died unexpectedly on July 12, 1924. Dr. Broome was born near Utica, N. Y., in 1867, and practiced medicine in Utica until 1900, when he became associated with D. Appleton and Company, as editor of their medical department. About a year ago Dr. Broome organized his own business for the publication of medical books.

HENRY MOELLER, M.D.

Dr. Henry Moeller, of New York, died at his home August 5th, at the age of eighty-two years. Dr. Moeller was born in Germany, coming to this country at the age of eighteen. He was graduated from the College of Physicians and Surgeons in 1871, and became connected with the Hospital for Ruptured and Crippled Children. He was considered an authority on kidney and heart diseases, and identified a robber who attacked him in his office, posing as a patient, through a peculiarity in his heart action. Dr. Moeller was physician to many prominent people, among them the Rockefellers. He rarely made house calls, insisting that his patients call on him, and await their turn in his office.

Letters to the Editor.

THEFT OF SURGICAL INSTRUMENT

New York, *August 1, 1924.*

To the Editor:

On July 14th a tall well-dressed, smooth-shaven man with brown hair and of good appearance, about thirty years of age, called at my office and said that he was with the Kny-Scheerer Company.

He said that he wished to use a Roy Paquelin cautery for his father and remembered that I had taken one to him for repairs. He gave the name of Thomas J. Tibbets and said that he would return the cautery on the following day. This he has not done and the Kny-Scheerer Company know nothing of him.

The platinum points of this old-fashioned cautery are now valuable. The man expressed an undoubted familiarity with the subject of cauteries and other surgical instruments.

Robert T. Morris, M.D.

News Items.

Industrial Hygiene.—The personnel of the recently appointed Advisory Committee on Industrial Hygiene of New York State is as follows: Dr. W. Gilman Thompson, chairman; Hon. Matthias Nicoll, Jr., Hon. Frank J. Monathan, Dr. Orrin Sage Wightman, Dr. Charles L. Dana, Dr. James Alexander Miller, Dr. George M. Price, Dr. Louis I. Dublin, Dr. Leland E. Cofer. The first number of the *Industrial Hygiene Bulletin,* published by the New York State Department of Labor, Bernard L. Shientag, Industrial Commissioner, was issued in July.

The Department of the Interior, through the Bureau of Mines, is making an investigation of health conditions in the oil fields.

Research in Vitamines.—Prof. Wilhelm Stepp, of the University of Giessen, is to spend six months in this country in the study of vitamines, at the invitation of the Rockefeller Foundation.

Quaker Relief Work.—The Executive Secretary of the American Friends Service Committee Wilbur K. Thomas, has gone to Europe, and in company with the head of the English Quaker Relief Society, will visit Austria, Germany, Russia, and Poland.

International Prize.—A prize of thirty-five hundred liras is to be awarded for the "best orthopedic work or invention." The contest is open to all physicians. Application should be made to the president of the Rizzoli Institute, Bologna, Italy, the closing date of the competition being December 31, 1924.

State Tuberculosis Death Rate Higher for 1923.—Provisional figures for 1923 indicate a decrease in the death rate from tuberculosis in New York City from 88.3 to 86 in 100,000; in the rest of the State an increase from 88.1 to 89.9. The number of cases reported was 2,141 less in New York City than in 1922, and 269 greater in the rest of the State.

Virginia Board of Health.—A new board of health, of seven instead of fourteen members, has been appointed for the state of Virginia. The following are the physicians chosen: Dr. Henry M. Miles, Norton; Dr. W. M. Smith, Berryville; Dr. Guy R. Harrison, Richmond; Dr. William T. Graham, Richmond; Dr. Lawrence Royster, University of Virginia, Charlottesville; Dr. John T. Daniels, Cape Charles. Dr. Miles is the only member continued from the former board.

State Hospital Statistics.—The State Hospital Commission recently reported to the Legislature that total disbursements of the department during the year 1923 were $14,386,000, a decrease of $1,660,000. Income from paying patients amount to $1,378, the largest sum ever collected in one year. Overcrowding certified capacity to the extent of 23.7 per cent. was found, but it is expected that the new construction provided in the recent bond issue will greatly improve this condition.

Child Labor in New York State.—According to statistical data form January 1, 1910, to December 31, 1920, which have been recently compiled by the State Department of Labor, there were at the close of that period 47,024 fourteen and fifteen year old children gainfully employed in the State of New York. This number represents 14 per cent. of all children of those ages in the State. In the first and second class cities the percentages of working children of this age group is as follows: New York, 18 per cent.; Rochester, 17; Buffalo, 15; Syracuse, 14; Albany, 11; Yonkers, 11 per cent. In 1923 the number of children found illegally employed was 3,561, of whom 1,023 were under 14 years of age. The proportion of girls entering clerical positions and of boys in manufacturing and clerical work has greatly increased during the ten years period.

New York State Appropriations.—The State Board of Estimate and Control has apportioned $12,402,500 for the construction of new buildings at State hospitals for the insane and other State institutions. This sum represents the first year's proceeds of the recent $50,000,000 bond issue. In detail, there was appropriated $1,930,000 to the Kings Park State Hospital, to complete buildings for ex-service men with mental disorders, giving a capacity of 1,000; $3,500,000 for the completion of the Creedmoor Division of the Brooklyn State Hospital; $2,570,000 for converting the former State prison at Wingdale into an institution for the insane; $60,000 for staff quarters at Manhattan State Hospital on Ward's Island; $1,000,000 for the enlargement of the Matteawan State Hospital for the Criminal Insane, the most seriously overcrowded of all State hospitals; $1,812,500 for the enlargement of Letchworth Village; and $295,000 for enlarging the State Hospital for Crippled Children at West Haverstraw. The balance of the funds will be expended in enlarging the Rome State School for Mental Defectives and the Craig Colony for Epileptics at Sonyea. The allotments follow closely the recommendations made by the Citizens' Committee on Protection of the State's Unfortunates, appointed by the State Charities Aid Association.

Hospital News.—The New York Hospital and St. Vincent's Hospital have purchased additional property.

The West Baltimore General Hospital, capacity one hundred and fifty beds, has been dedicated.

The Massachusetts General Hospital, Boston, is planning a $300,000 improvement and enlargement of the Bulfinch Building.

The Boston City Hospital is to be enlarged by a hundred bed maternity building, modeled after the Lying-In Hospital.

The Swedish Immanuel Deaconess Hospital, of Omaha, will erect a $200,000 addition.

The new Wilder Dispensary Building of St. Paul is now ready for occupancy. This is a four story brick and stone building, erected by the Amherst Wilder Charity.

Through an ordinance setting aside $4,000,000 of the next municipal loan of Philadelphia, it will become possible to raze the present buildings of the Philadelphia General Hospital and erect a new 2,100 bed hospital to replace it. It will also be possible to remove the 1,400 insane patients now at Blockely to the City Hospital for the Insane at Byberry.

The cornerstone has been laid of two hospitals of the Western-Reserve University-Lakeside Hospital group. These two buildings will cost $3,300,000, and will be finished in 1925.

A permanent recreation building at the Walter Reed Hospital is provided for by a Red Cross appropriation of $150,000.

The contract has been awarded for the new Sydenham Post-Graduate Hospital, at 123d Street and Hancock Place, New York, the cost being around a million and a quarter.

The cornerstone has been laid for the Somerset Hospital, Somerville, N. J., to be built at a cost of $400,000, and to serve Somerset and Hunterdon counties.

Both Bellevue and Fordham hospitals in New York are to have new nurses' homes.

Personals.—Dr. A. O. Oliver has sailed for Europe, to demonstrate American methods of correcting jaw defects in children, in clinics to be held in London, Amsterdam, and Paris.

Dr. Mark Hornstein has been appointed attending obstetrician at the Jewish Memorial Hospital.

Dr. James W. Smith has been appointed attending ophthalmologist at the New York City Hospital.

Dr. Charles B. P. Kelly of Jersey City, president of the Hudson County Medical Society, has been appointed a member of the state board of medical examiners.

Dr. Anna Koslow and Dr. Pauline Seller, graduates of the University and Bellevue Hospital Meeifal College, have received appointments as interns at the Bronx Hospital,—the first women to serve at that hospital.

Dr. John A. Foote, of Washington, who is professor of diseases of children at Georgetown University School of Medicine, has been elected a member of the board of trustees of the National Geographic Society.

Dr. Samuel T. Darling, of Baltimore, who is a member of the International Health Board, at present engaged in field studies of malaria control in Georgia, has been elected president of the American Society of Tropical Medicine.

Dr. Harvey F. Smith, of Harrisburg, Pennsylvania, has been awarded the honorary degree of doctor of science by Bucknell University.

Dr. Obadiah H. Sproul, of Flemington, Pennsylvania, a graduate of the University of Pennsylvania Medical School in 1866, recently celebrated his eightieth birthday. Doctor Sproul is a former president of the state medical society.

Dr. Eliza M. Mosher is chairman of the Cleaner Brooklyn Committee, planned to enforce the law regarding cleanness in the public parks.

Dr. Frederick E. Sondern, of New York, has been elected vice-president of the American Society of Clinical Pathologists.

Dr. Florence R. Sabin, professor of histology at Johns Hopkins Medical School, has been appointed a member of the scientific staff of the Rockefeller Institute.

Dr. Descum C. McKenney was elected president of the Alumni Association of the University of Buffalo.

Foreign Correspondence

VIENNA LETTER

(From our own correspondent)

VIENNA, *July 1, 1924.*

PROFESSOR HOCHENEGG'S CHARGES AGAINST THE SURGEONS OF VIENNA

The medical profession and public opinion as well have been greatly agitated by an uncommon event. Professor Hochenegg, director of the second surgical clinic of the University of Vienna, stated in a lecture to his students that certain doctors were circulating unfounded calumnies about him, saying that he was not modern enough, that his weakened sight prevented him from performing successful operations, that he was too conservative in his thinking, and owing to this that he failed to adopt up to date methods. Professor Hochenegg said that the reason for this was that he was one of those old fashioned behind the times men, who could not descend to sharing the fees received from patients for operations performed with the family doctor who sent the patient to him. His feeling of dignity protested against dichotomy. Besides this Hochenegg stated that at present in Vienna family doctors patronized always those surgeons from whom they get their regular commission for the cases submitted. He even went so far as to state that there were doctors who were capable of sending patients to surgeons when operations were not indicated, simply to make money.

It is but natural that the whole medical profession is upset and embarrassed at the statements of Hochenegg, which were rendered still more serious by the fact that the statements were told publicly and therefore widely circulated in the lay press with sharp criticisms. Some newspapers demanded a thorough investigation of the cases in which patients were operated upon without due indication, and the culprits punished.

The physicians of Vienna have held several conferences and resolved that Professor Hochenegg shall prove the correctness of his statements with substantial evidence. The leading daily papers have interviewed the most distingusihed medical men in Vienna on this topic; all of them gave their views on the subject, condemning Hochenegg for accusing a whole staff without mentioning singly those whom he knew were vicious, thus giving a broad field to conjecture. The most prudent and sincere opinion was that of a famous Vienna surgeon, who did not reveal his identity. He said: "The Vienna doctors are complaining of their practice making retrograde steps. The cause of this, in the first place, is that in latter years a great many new doctors have settled in Vienna. At present there are about 4,500 medical men living in Vienna, among them many university professors, lecturers, and specialists. It is not to be wondered at, therefore, if the ratio of patients and doctors is very small. Also the number of patients has decreased, not only on account of improvement in hygienic conditions, but also because of the impoverishing of the population, doctors are not consulted in every case. The number of foreigners coming to the Austrian capital to consult doctors has also considerably decreased. The reason of this is easily found in the fact that Vienna is at present one of the most expensive cities of the world.

The doctors of Vienna are very desirous that this serious accusation of Hochenegg should be cleared away; the medical profession feels the weight of this accusation, and fears are entertained that Vienna, once recognized as the centre of medical science and art, should suffer in its reputation. It is generally demanded that light be thrown, as quickly as possible, upon this dark blot on the character of Vienna medical men. At present the case is in the able hands of the Vienna Medical Chamber, the only competent forum to investigate the matter.

The object lesson of this whole affair is that in the Vienna University for the past decade war has been waged between two medical parties. One party is of the opinion that every old medical professor, if he is provedly of Aryan descent, is entitled to leave his chair to his son or nephew as an inheritance; the other party would like to see in the professorial chairs of the university the fittest men, even if they happen to be of unsettled religion. The battle of the clericals and freemasons is carried on in the university, and in this fight the weapons are changing from time to time. Such a weapon is the discovery that Hochenegg (of pure Aryan pedigree) could produce little proof beside his accusation; he simply stated the fact that the clientele of certain medical professors was strikingly large.

LATIN AMERICA LETTER

(From our own correspondent)

CANAL ZONE, *July 1, 1924.*

EXTENSION OF THE JURISDICTION OF THE UNITED STATES

One of the problems which faces the authorities of the Panama Canal who have an interest in the future operations of this great international waterway, is the way in which enough water may always be available for lockages. During the wet season there is enough and to spare, in fact at that time there has to be under the the present system of water storage, a considerable water wastage. But when the dry season with constant Trade winds and long continued droughts arrives, there are enormous losses from evaporation and while the storage facilities are sufficient for the present ship traffic and the average dry year, should there be a considerable increase in the number of ships passing through or should there be a very unusual drought the amount of water on hand might prove too small in proportion to the load. It is with a view to preventing such a situation as this that the districts of San Juan de Pequeni and El Vigia around the headwaters of the Chagres River have been taken over by the United States authorities and will soon disappear under water to give way for new improvements for the Canal.

Recently the Washington government informed the Panaman government that for the purpose of carrying out a project of improvements for the Canal it would be necessary to take over about twenty-two

square miles of Panaman territory around the headwaters of the Chagres, a rural district devoted to agriculture and stock raising. This was complied with and a joint Panaman and American Commission visited the territory and conducted the ceremonies of cession and reception, giving instructions to the inhabitants as to the new laws by which they will henceforth be governed. The local officials and police officers received instructions as well as the school teachers and district authorities. Since the Canal Zone is really "dry territory" all bars and liquor stores were closed and sealed after an inventory had been taken of the stock on hand.

The Panama Canal government will construct a dam across the Chagres River at Alajeula which will permit the formation of an artificial lake extending as far as the mountains surrounding the districts of San Juan de Pequeni and El Vigia. This will serve as a reservoir to retain the water which is ordinarily wasted during the wet season, thus ensuring an adequate supply of water at all times for the operation of the Canal. A considerable number of the inhabitants who have been dispossessed will move to Gatuncillo in Panaman territory near Gamboa. That the movement of this population will constitute a new sanitary problem is undoubted since it contains a good many malaria carriers.

IMPROVED SANITATION FOR INTERIOR TOWNS

Pointing out that the sanitation of the interior towns of the Republic of Panama is not such as to invite immigration and that the lowering of the health rate of these towns is largely responsible for their backwardness and poor financial condition, the Rotary Club of Panama City is urging that the National Government install modern water supply and sewage disposal systems in Penonome, Santiago, Las Tablas, Chitre and La Palma. Panama, Colon, Gorgona, Matachin and Empire are all well supplied with water and their sewage disposal systems are satisfactory. It is argued that these benefits should be extended to other towns. This seems the more logical, since the Government is repairing the cemeteries at many interior places.

THE NATIONAL TUBERCULOSIS SANATORIUM

Dr. M. Gonzalez Revilla, official physician of Chiriqui Province, has addressed a letter to the Minister of Public Works urging that the National Sanatorium be located at Los Potrerillos or El Volcan. Chiriqui Province is one of the most beautiful parts of the Republic and is possessed of a delightful climate. Potrerillos is the terminal station of one of the branches of the Chiriqui Railroad and El Volcan, which has a greater elevation, is to be connected with Conception, on the railroad, by a fine automobile road voted by the last National Assembly. These sites as well as the Anton Valley, San Carlos, Pacora and Ceremeno are all under consideration by President Porras in whose hands the final selection of a location for the sanatorium rests.

PROJECTED HOSPITAL DEFEATED

At the town of Bocas del Toro, the place by the way where Columbus careened his ships on his third voyage, the Municipal Board met recently to consider a project to rebuild the old hospital and make it into an uptodate structure. The funds of the town were shown to be ample to meet the expenses but the board in its wisdom decided that it would be better to utilize them in increasing the wages of the town employees. Also, this is the year when we in Panama elect a President.

DR. POWERS VISITS THE ISTHMUS

Dr. L. M. Powers, the veteran Health Officer of Los Angeles, Cal., recently paid an extensive visit to the Panama Canal Zone. Under the guidance of Dr. J. L. Byrd, Health Officer of Colon, he inspected the work which is being done by the sanitary forces in the terminal cities, and in company with Dr. Lopez del Valle and Dr. Hugo Roberts, of Cuba, he went through the Miraflores Water Purification Plant.

A NEW CHIEF QUARANTINE OFFICER

Surgeon C. P. Knight, United States Public Health Service, accompanied by his wife and family, arrived on the steamship *Cristobal* on February 5, 1924. Dr. Knight is to relieve Surgeon William Colby Rucker, United States Public Health Service, who has been Chief Quarantine Officer since October, 1920. Dr. Knight was appointed Assistant Chief Quarantine Officer by the Governor of the Panama Canal since Dr. Rucker is not to be relieved until the close of the Conference of the Maritime Quarantine Authorities of the West Coast of South America of which he is the Secretary General.

HEALTH CENTRE FORMED

As one of the results of the recent visit of Miss Sally Lucas Jean, of the American Child Hygiene Association, a health centre has been formed in connection with the Balboa Club House. Health plays are being given by the children and several meetings of mothers have been held. The movement not only has the hearty backing of the Canal Zone government but has been taken up by Mrs. Jay J. Morrow, the wife of the Governor, and other prominent women.

DRUG TRAFFICKERS APPREHENDED

It is only by the most constant vigilance on the part of the various customs and other authorities that the traffic in habit forming drugs is curbed. In several of the surrounding countries there are distributing stations for the various Latin-American countries and it is an unending fight to keep these criminals from introducing their wares and spreading the drug habit among the native population. Recently the capture of two *cocaineros* not in any way connected in their operations, served to signalize the very great danger with which this traffic threatens those countries which have a large ignorant indigenous population. All over Central and South America it is the native Indian stock which supplies the labor market and if the integrity of this class is impaired by drugs the economic dissolution of this part of the world will follow. Panama has been most vigorous in the detection and punishment of the purveyors to the drug habit and it is hoped that some international cooperative scheme may be put in force which will definitely put these malefactors against the health and prosperity of these countries out of business.

PRENATAL WORK IN PANAMA

The Health Departments of the Canal Zone and the city of Panama are now carrying on work to the

end that every mother may be made comfortable during pregnancy and that her labor may be safe and her convalescence uneventful. Upon the Canal Zone, each District Physician is ready to give advice and instruction and when the time of delivery arrives the best of care and attention are available at Colon and Ancon Hospitals. In Panama City the prenatal and baby clinics of Santo Tomas Hospital are rendering increasingly valuable service. Connected with the clinic two native women act as nurses. The Panama Red Cross also conducts a baby clinic where good work is being done. In Colon, in addition to the services of Colon Hospital and the newly opened Panama Hospital, the Women's Club conducts a prenatal and baby clinic in the office of the Health Officers and employs a visiting nurse who works in cooperation with a visiting nurse attached to the Colon-Cristobal Health Office. As a result of these efforts, the infantile death rate which formerly was terrific, is being steadily reduced.

WASHINGTON LETTER

(From our own correspondent)

Washington, *July 1, 1924.*

HEALTH OFFICIALS WAR ON FLIES

Dr. W. C. Fowler, Health Officer of the District of Columbia, has launched a campaign against the housefly, and will distribute posters to warn the public of their danger to health. The delayed summer may have a deterrent action on flybreeding, but Washington has always suffered unduly from flies in its public markets and elsewhere.

MEDICAL SOCIETY ELECTION

Dr. Elijah W. Titus was elected president of the George Washington University Medical Society at a meeting held on the evening of May 18, 1924, in the medical school building of the University, H and Fourteenth Streets Northwest. Dr. Jesse T. Mann was elected vice-president, Dr. Boyce R. Bolton re-elected secretary, and Dr. Thomas C. Thompson made treasurer. The retiring president, Dr. Paul S. Putzki, delivered the year's presidential address, discussing The Surgical Aspect of Diseases of the Pancreas. A buffet supper followed the meeting.

MEETING OF THE DISTRICT MEDICAL SOCIETY

A discussion of smallpox, now prevalent in Washington, constituted the program of the Medical Society of the District of Columbia at the weekly meeting in the Medical Building, 1718 M Street, Northwest, at 8 o'clock, May 28, 1924. Dr. Frank Leech read a paper on Clinical Diagnosis, Dr. J. W. Lindsay on Laboratory Diagnosis, and Dr. H. C. Macatee on Prophylaxis. The discussion was led by Dr. J. P. Leake, of the Public Health Service.

For several months smallpox has been occurring in the District, and three new cases of smallpox, all mild, were discovered on May 21, 1924, and brought the number of active cases under treatment in the District up to nine. One woman patient in a hospital was discovered suffering from the disease, and the ward was isolated. A colored woman, also suffering from the disease, was apprehended when she appeared at the dispensary of a hospital for treatment. A colored man was found with smallpox in Anacostia. Health authorities also have another man under observation. Approximately 150 cases have occurred since the beginning of the outbreak. All have been among unvaccinated persons, and for the most part are among newly arrived colored laborers from the Southern States.

RETIRED MEDICAL OFFICERS' PAY

The Hull bill, which aims to correct an injustice to the older retired medical officers of the army, navy and public health service, is now on the House calendar. The pay act of 1922, so just and equitable in other respects, unfortunately discriminates against these most deserving officers, veterans, many of them having more than forty years' active service to their credit—men who have served faithfully through four great wars, including the World War. These are the officers who, because they happened to be retired before July 1, 1922, are denied the benefit granted by the pay act of 1922. These veteran officers have reason to be dissatisfied. They see officers who were always their juniors during their active service now receiving the deserved increase granted for long and faithful service, which recognition is denied to them. By repealing the discriminating language, officers of equal rank and equal service will be treated alike and relieved of the embarrassment and sense of injustice under which they now suffer.

INDUSTRIAL STATUS OF THE DISTRICT OF COLUMBIA

The District of Columbia is the stepchild of the Nation. Disenfranchised with regard to local matters, its inhabitants have no voice in its government. The various commercial organizations and neighborhood societies meet and resolve; they appeal to the Commissioners (who are appointed by the President, "by and with the consent of the Senate"); they even appeal to the District of Columbia Committee of the House of Representatives, but when it comes to essentials they are impotent politically. The House of Representatives is the Board of Aldermen of the City of Washington, and hence, the citizens of some rural Congressional District has greater power in the regulation of the municipal affairs of the Nation's capital than does the largest property holder therein. True it is that the Federal Government pays its forty per cent. of the local taxes, but the upkeep of this most beautiful city in the world is so heavy that the sixty per cent. remaining is a genuine burden, reaching a higher taxation valuation and rate than in most cities of the same size. The result is a lowering of the civic pride, and an absence of that community spirit which is met elsewhere. This reflects itself in things medical and the Washingtonian, who must maintain a residence elsewhere in order to vote, has relatively little interest in the Municipal Health Department and the local hospitals. The great industry is the government workshops, where underpaid clerks make futile black marks on white paper all day long; the remainder of the population lives off of each other and the visitor. The result is a "hard collar" population of nonproducers, and a civic attitude of mind unlike that of any other great city. Hence, while it is a pleasant and beautiful place in which to dwell, it has no industrial existence, other than clerical and mercantile, and no factory population, while of municipal entity and consciousness it has none.

PARIS LETTER

(*From our own correspondent*)

PARIS, *July 25, 1924.*

CRAVINGS

Professor Carnot in a recent lecture upon food emphasized some points that can be useful to any practitioner. Contrary to general belief, likes and dislikes in the matter of food depend more upon mental than upon physical conditions. The palate is influenced by the temperament, not the temperament by the palate, and to the doctor a knowledge of his patients' favorite dishes is a sure index of their mental and emotional state. Certain temperaments create cravings for certain forms of diet, and one need not be a doctor to gauge the mentality of the man whose favorite foods are roast beef, potatoes, and suet puddings and whose favorite drink is beer. He would naturally be credited with a less sensitive palate than the man to whom soft roes are the most attractive dish and champagne the only drinkable beverage. But the difference is really a difference of temperament.

If the beefeater despises the epicure for his fastidious taste, he is actually despising him for possessing a more delicately sensitive mentality; and the epicure who accuses the beefeater of being a temperamentally coarser creature than himself has science on his side. Because a certain form of diet is most appetizing to the palate, it does not follow that it is the one best suited to the requirements of the body. Anyone, for instance, susceptible to great mental or emotional changes naturally craves for a stimulating diet—the very diet to be avoided. The temperament which impels a person towards the cultivation of psychic powers invariably produces a craving for fruit, but it is quite possible that such a diet might be totally unsuitable.

The palate rarely undergoes any radical change. What appeals to it in childhood usually appeals to it in later life. A man may not, perhaps, take the same delight in sucking sweets at the age of forty as he did at the age of ten, but he probably takes his sugar in the form of whisky. There is a broadening of taste to correspond with the broadening of the mind, but only a radical change of temperament could produce any great variation in the likes and dislikes of the palate. There is, of course, such a thing as an acquired taste, but the change that is brought about is primarily a mental change. The change of the mental attitude from "I don't like it" to "I shall like it" would soon produce a corresponding change in the palate. Sudden changes in the palate are the common result of sudden changes of environment, and under the influence of unusual emotions people will often develop a craving for foods which under normal conditions they cannot touch. To make the best of yourself you require good food, good rest and recreation, and the less alcohol the better. Good food and rest enough, but not too much of either. You need much less food than one would imagine to keep you in condition. Most of us habitually eat too much, overloading the system, and dulling the brain. Don't do it, but take enough. While eating give your attention to it, and enjoy your food. That makes for good digestion; while eating mechanically and thinking business does not. Particularly make sure that your food contains a good supply of the essential vitamines. In this respect you will not go short, if you exhibit a partiality for green vegetables and tomatoes. These are the chief ones, but there are many others, such as potatoes, butter, fresh meat, especially the fat, wholemeal bread, unpolished rice, fresh eggs, new milk, lemon, and other fruit juices.

AMERICAN MEDICAL SOCIETY

Under the presidency of Dr. Edmund L. Gros, the American Medical Society of Paris met at the American University Union last Wednesday night (June 18th) to listen to an interesting lecture by Professor Claude, translated into English by Dr. Dax. Professor Claude described new methods of exploration of the nervous system in cases of mental excitation and depression, which made it possible to predict impending brain storms, as also to differentiate between mental disturbances of a permanent or a temporary character. He has made a careful study of the oculocardiac and solar reflexes in these cases, and showed some interesting conclusions. The oculocardiac reflex is a slowing of the heart during gentle pressure on the eye balls, which exists in certain forms of nerve disturbance and not in others. Such a reflex is positive in impending melancholia, epilepsy, and absent in psychosis due to intoxications and infections such as the insanity sometimes following childbirth. Professor Claude's communication is of great clinical importance, throwing a new light on obscure disturbances of the brain and nervous system.

VENEREAL DISEASE

Speaking on the ravages of venereal disease, Sir James Crichton-Browne stated at the conference of the Sanitary Inspectors' Association at Paris, that syphilis caused 2,023 deaths in England and Wales in 1920, and other venereal diseases 2,103. No fewer than one tenth of the people in our large towns, he said, were infected with syphilis and a much larger proportion with gonorrhea. The latter was prolific of sterility, blindness and of rheumatic and joint affections. Syphilis was the direct cause of the vast number of cases of abortion, miscarriage, stillbirth and infant mortality, and as a hidden assassin was undoubtedly responsible for a large number of deaths which were attributed to other causes.

"Syphilis," he said, "is an infectious disease due to a specific organism which we can show you on the kinematograph, darting and wriggling about, serpentlike, on its malign career. That organism can be intercepted in its career. The disease can be prevented. If you ask why it is not prevented the answer must be because of neglect on the one hand and ecclesiastical prejudice and shortsighted morality on the other. The proper and infallible preventive is chastity and marital fidelity, but these have failed lamentably. To proclaim a new antidote to a deadly poison is not to encourage people to run the risk of swallowing the poison. There is the clearest and most definite medical evidence that the spread of venereal disease can be prevented by the adoption of methods of selfdisinfection. We must have the suppression of unqualified quacks and herbalists. We must have a network of clinics throughout the country; hospitals for the prolonged treatment of women and girls, and laboratories for investigation.

Book Reviews

INTERNAL SECRETIONS

The Internal Secretions. For the Use of Students and Physicians. By Dr. Arthur Weil. Authorized Translation of Third German Edition, by Jacob Gutman, M.D., Phar. D., F.A.C.P. New York: The Macmillan Company, 1924. Pp. 287.

This is one of the most useful books on general endocrinology which has been published. The point of view is practical throughout and the enthusiasm of Weil is communicated to the reader. The main value of the book is that function is given preference over gland, and this is of vital importance. For these and other valid reasons the general practitioner should find much use for this convenient volume. Doctor Gutman was the person upon whom the task of translation should naturally fall, for he has been for some time closely allied with the work of Weil. He has done a decidedly worthy job of it.

STERILITY

Fertility and Sterility in Human Marriages. By Edward Reynolds, M.D., and Donald Macomber, M.D. With Section on Determining Causes of Male Sterility, by Edward L. Young, Jr., M.D. Illustrated. Philadelphia and London: W. B. Saunders Company, 1924. Pp. 285.

In this book the subject is handled from the physiological as well as the biological point of view. The organic conditions are considered apart from those arising from physiological causes. The section dealing with the marital habit is exceptionally well handled. The chapter on impotence on the other hand is somewhat brief and far from satisfactory for a book of this type. The treatments advocated for the various organic conditions is quite comprehensive. On the whole it is a book well worth reading.

HEREDITY

Genetics. An Introduction to the Study of Heredity. By Herbert Eugene Walter. With 92 figures and diagrams. Revised Edition. New York: The Macmillan Company, 1922.

Walter has had in mind a large class of readers and students to whom he addresses his comprehensive review of the subject of heredity or genetics. He gives a survey of the history of the subject since Darwin set forth the idea of a genetic development of species out of that which had preceded. He discusses the various theories which often conflict but which, nevertheless, have cooperated in the furthering of investigation into the nature of life and its progress. He points out the most important facts in this subject of heredity while he gives the history of their discovery. He shows the practical application of these facts to the various forms of life, with a particular emphasis where the problems involved become of gravest significance. This is in the human species, where the writer stresses particularly the great importance of heredity among the other chief factors of life. He represents these graphically as forming a triangle whose three sides are environment, response, and heredity, the last occupying the basic position. He brings to his readers, furthermore, the great responsibility which this subject entails through a discussion of the evils introduced and retained in the human species as well as by indication of the control that may be brought about. In a book of so considerable a size in its discussion of these many points he cannot do more than briefly suggest the chief avenues of relative promise for eugenic control of heritable factors. He acknowledges the difficulties of the task. Yet he might have offered further suggestion which would have made these difficulties more understandable and also have given more promising approach to them. This would be in the fields designated by the other sides of his triangle. Important as heredity is, there is danger of laying upon it such emphasis that the responsibility and the opportunity which come through environment and chiefly through the factor of individual response are allowed to slip out of sight. Present day psychology has opened a promising field of study of individual response and of its readjustment. Through this much is gained, for the individual at least, in definite work upon the interaction of the three factors, environment, response, and heredity. Emphasis upon this psychological point of view throws light also upon the more general facts of heredity themselves as it aids eventually, through the factor of response, in the larger eugenic control.

ANESTHESIA

The Science and Art of Anesthesia. By Colonel William Webster, D.S.O., M.D., C.M. St. Louis, Mo.: C. V. Mosby Co., 1924. Pp. 214.

The keynote to the book is given in the preface, "To place before the medical student and the physician in general practice, who perhaps gives only an occasional anesthetic, in concise form but not so brief as to leave matters imperfectly explained, a small manual on the subject of anesthesia."

The history is accurate, concise, and interesting. The chapter on physiology is unusually good and many professional anesthetists would cease cyanosing and asphyxiating their patients if this chapter were carefully read: "The ganglion cells of the cerebral cortex are thus shown to be exceedingly sensitive to lack of oxygen. This indicates that a degree of narcosis just sufficient to paralyze consciousness is the desirable one and not a deeper narcosis which completely inhibits oxidative processes and may thus, if prolonged, do permanent injury to the brain."

The chapter on chloroform is probably the weakest in the book. The danger from this drug in administering it, especially to young children, is not sufficiently stressed. The chapters on ether and nitrous oxide are good. In the last paragraph of the chapter on nitrous oxide the statement that "Ether is invariably the anesthetic used for operating in many of the sanatoria for tuberculous patients" seems out of place and is entirely at variance with most writers on the subject. The chapter on ethylene is short, but to the point—as is also the chapter on ethyl chloride, ethyl bromide and somnoform. The special physiology of other drugs, ethyl chloride, ethyl bromide, somnoform and special pathology of

local and spinal analgesia make these chapters valuable to specialist as well as to the occasional anesthetist. Shock—preliminary and postoperative treatment (medicolegal aspect) and other special chapters are dealt with in a masterly manner. The style, brief, direct, concise, is attractive to those desiring a working knowledge of anesthesia. On controversial points, such as heating anesthetic gases and preliminary medication, the author is fair and gives both sides of any question without prejudice. The book, on the whole, is well worth reading, by the occasional anesthetist and by the specialist.

DISEASES OF MIDDLE LIFE

Diseases of Middle Life. The Prevention, Recognition, and Treatment of the Morbid Processes of Special Significance in this Critical Life Period. Comprising Twenty-two Original Articles by Various Eminent Authorities. Edited by Frank A. Craig, M.D. Two volumes, Illustrated. Philadelphia: F. A. Davis Co., 1924.

This series of monographs by various well known authors should prove of distinct value to the medical profession. Many new divisions and groupings have come to be recognized, including the two ends of the scale, pediatrics and geriatrics. Now we have the larger intermediary range classified. Naturally this is but a link between and in a way tends to add to the concept of man as a member of a categorical pigeon-holed machine. However, it is just as well, as we will be more than ever forced to the position of regarding man as a complete entity, fulfilling his biological functions in relation to his environment, internal as well as external.

The point is well taken that in middle age we most frequently find signs of a giving way of the machine—here and there, and often it is of prime importance to be on the lookout so we may save the mechanism from further ravages in later life. We could well go a step further and state that the best time to study the breakdowns which occur in later years should be forestalled during infancy and childhood, but alas we have travelled but a little way on this more sensible route. Perhaps the best work along these lines has been done in the field of mental medicine, in accordance with the teachings of the psychoanalytic school. The contributors to these two volumes have been selected with rare judgment, and the subjects are presented simply and lucidly.

DISEASES OF THE BREAST

The Diseases of the Breast. By Willmott H. Evans, M.D., B.S., B.Sc., F.R.C.S. With 600 illustrations, of which Fifteen Are Colored. London: The University of London Press, Ltd., 1923.

An exceedingly fine piece of work filling a need. The pathophysiology of the mammary gland has in the past scarcely received the recognition which the subject justified. Evans has presented the topic in an adequate fashion. He discusses the physiology, anatomy, pathology and treatment of the various diseases and anomalies of the breast. Among the subjects of common interest, which he discusses, are mastitis, abscesses, injuries, tuberculosis, syphilis, the various skin disturbances and new growths. These latter are given careful consideration, and the entire subject is gone over completely. There can be no doubt that from a purely practical point of view a work of this kind is of great value.

DIABETES

Management of Diabetes. Treatment by Dietary Regulation and the Use of Insulin. By George A. Harrop, Jr., M.D. Introduction by Walter W. Palmer, M. D. New York: Paul B. Hoeber, Inc., 1924.

This manual is intended for physicians, nurses and dietitians and brings the results of the experiences gained in a course of instruction given at the Presbyterian Hospital, New York City. The authors feel that it is necessitated by the recent advances made in insulin therapy and it contains many practical pointers for those who are in charge of diabetic patients. After discussing the normal metabolism and acid base mechanism and their derangements in diabetes mellitus and in acidosis, the general principles of dietary regulation and insulin treatment are outlined. The practical problems in the use of insulin and its use in acidosis are discussed. The complications of diabetes are taken up briefly and clearly. The chapter on the diet of the diabetic patient, as well as the food tables, are very practical and useful. Only those important methods of blood and urine analysis are given as have been found to be practical and not too difficult to carry out, such as the tests for the alkaline reserve of the blood plasma, the Folin and Wu method of determining the blood sugar, the ferric chloride and the nitroprussic tests for ketones, the Benedict qualitative test and the fermentation test for glucose in the urine and the acid heat test for albumin in the urine. The aim of the authors is to give only well established and practical information and it has been well done.

A YEAR BOOK OF TREATMENT

The International Medical Annual. A Year Book of Treatment and Practitioner's Index. Forty-second year. New York: William Wood & Co., 1924.

The *International Medical Annual for 1924* appears as usual in dictionary form with numerous excellent illustrations, fulfilling its purpose of serving as a kind of serial textbook of medicine for the general practitioner in whatever part of the world he may be. The specialist also is furnished in brief articles with news as to the way in which matters are moving in special branches of medicine other than his own. An evident attempt has been made, and successfully, to give a general impression of the direction in which the art and science of medicine is progressing. This is done through statement of fact and through criticism and voicing of opinions by the authorities who contribute the articles. It is undeniable that the drift of medicine today is toward prevention of disease. Prevention is based on the premise that all diseases are of course due to a cause or causes; that these should be made the subjects of research; and that the knowledge thus gained should be applied to the abolition of these causes. The study of bacteriology has in recent years given much impetus to this view of disease, which nevertheless has been held in abstract form since the dawn of medical study. An examination even somewhat cursory of this volume of the *International Medical Annual* cannot fail to reveal the progress of this spirit of prevention.

Although the form of the volume is that of a dictionary of medicine, with subjects arranged and dis-

cussed in alphabetical order, the usefulness of the book is greatly enhanced by a detailed general index at the end, giving the subjects of the longer articles in heavy type.

CONGENITAL SYPHILIS

Abstracts Secured in the Compilation of Vereneal Disease Information and on File in the Division of Venereal Diseases of the U. S. Public Health Service. Compilation No. 2. Washington, D. C.: Government Printing Office, 1924. Pp. 111.

In the author's index of these abstracts are noted the names of the leading syphilographers of the world. Aside from these authorities, there appear also the names of a number of leading specialists in other fields, such as obstetrics and pediatrics, whose work renders these observations in congenital syphilis of much value.

These abstracts should be helpful for reference, as the entire subject is well covered by many observations from many different clinics in this country and Europe. For example, if it is desired to ascertain the latest prenatal treatment of congenital syphilis, one has only to turn to this chapter and find in concise form the methods employed in at least nine different and widely separated well run clinics. Statistics abound throughout but are presented in a manner less nauseating than where they are usually encountered.

There are all told six chapters, with twelve subdivisions of the chapter on stigmata, each subdivision dealing with a separate organ or symptom. In all, 196 authors are represented by the different abstracts, many of the authors contributing several papers. The index of authors is a valuable addition and refers by page number directly to the abstracts of their respective articles.

In this particular subject, such a compilation might prove to be of value in the hands of the laity, as certain of these abstracts show in plain language the value of the Wassermann test and the great good that is to be derived toward preventing congenital syphilis by early and well directed treatment of the pregnant mother.

DIAGNOSIS AND THERAPY

Irrtümer der Allgemeinen Diagnostik und Therapie sowie deren Verhütung. Herausgegeben von Prof. Dr. J. Schwalbe, Zweites Heft. Irrtümer der Ernährungstherapie. Von Professor Dr. Hermann Strauss. Grundirrtümer in der Ernährung der Kinder (jenseits der Säuglingszeit) und deren Verhütung. Von. Geh. Med.-Rat. Prof. Dr. Arthur Schlossmann. Mit. 11 Textabbildungen Elektrodiagnostik und Elektrotherapie (einschliesslich Diathermie). Von Professor Dr. Ludwig Mann. Irrtümer der Hydro-und Theramotherapie und deren Verhütung. Von Professor Dr. Alois Strasser. Orthopädie, Massage und Heilgymnastik. Von Privatdozent Dr. Georg Hohmann. Mit 30 Textabbildungen. Irrtümer der Balneotherapie und deren Verhütung. Von Med.-Rat Dozent Dr. Karl Zörkendörfer. Klimatotherapie. Von Dr. M. van Oordt. Leipzig: Verlag von Georg Thieme, 1923.

This is the second volume of the series *Irrtümer der allgemeinen Diagnostik und Therapie sowie deren Verhütung,* written by many collaborators under the editorship of Schwalbe. The first chapter deals with the general mistakes commonly made in dietotherapy in diseases of the digestive, vascular and renal systems, metabolic disturbances, febrile processes, senility and the feeding of preoperative and postoperative cases. The special forms of diet are also discussed. An appendix deals with the various types of artificial feeding. Schlossmann discusses the basic errors in the feeding of children beyond the infantile stage. Mann is assigned the subjects of electrodiagnosis and electrotherapy including diathermy. Strasser discusses hydrotherapy and thermotherapy. Hohmann deals with orthopedics, massage and gymnastics. The mistakes commonly made in balneotherapy and their avoidance is discussed by Zörkendörfer. Climatotherapy is exhaustively discussed by van Oordt. Each chapter has an up to date bibliography appended.

SCHOOL HEALTH SUPERVISION

Medical and Sanitary Inspection of Schools. For the Health Officer, the Physician, the Nurse and the Teacher. By S. W. Newmayer, A.B., M.D. Illustrated with seventy-nine Engravings and six Full Page Plates. Philadelphia and New York: Lea and Febiger, 1924.

This highly interesting and presentable volume represents the ideas and views gained by the author in an experience with his subject covering more than twenty-four years. Its purpose, as stated by the author, is to give knowledge rather than information, and the methods employed in various cities are offered as an "ideal" in the sense that they represent the best practice of the day in each of the various activities of school health supervision.

The work is divided into seven parts, administration, the school building and grounds, communicable diseases, physical defects, the health of teachers, mentality and allied subjects of school medical supervision. It will be seen that practically every phase of school inspection is covered, and a careful reading of the volume gives the impression of a thorough familiarity of the author with his subject and his ability to express himself clearly and concisely. In an interesting chapter on sex hygiene, the author discusses the problem of the advisability of teaching this subject to school children. His conclusion is that the preponderance of opinion is opposed to it, in view of the many difficulties and obstacles encountered in a proper handling of this delicate subject.

The publishers have joined with the author in producing a beautiful and instructive volume, which can be commended both for its thoroughness as well as for its style.

MILITARY HOSPITALS IN THE UNITED STATES

The Medical Department of the United States Army in the World War; Volume V: Military Hospitals in the United States. Prepared under the direction of Maj. Gen. M. W. Ireland, M.D., Surgeon General of the Army, by Lieut. Col. Frank W. Weed, M.C., U. S. A. Washington: Government Printing Office, 1923.

This volume supplies a record of the provision of military hospitals during the World War, and a description of their administrative operation. General topics incidental to the whole subject are first discussed, then the individual organizations. The volume opens with a history of the evolution of the military hospital, from the type of care described by Homer, when the wounded were transported by hand or chariot to the tents or "black ships" in the rear, to the military hospital in use when the United States entered the World War. Hospital procure-

ment, including discussion of methods, hospitalization schemes, and types of hospitals, is next taken up, followed by sections on construction and improvement; organization, administration, and control; and types of hospitals. The latter half of the volume is devoted to descriptions of individual hospitals, classified as general, base, embarkation, and debarkation hospitals.

Plans and statistical tables are numerous and excellent, as are the plates and illustrations. Each chapter is supplemented by a list of references, giving location of sources listed, and the whole volume is well indexed.

WORK AND LEISURE

The Interpreter's House. By Struthers Burt. New York: Charles Scribner's Sons, 1924. Pp. 445.

Deservedly, one of the best new novels. For with a commonplace story and unostentatious style. Struthers Burt gives us a few months of the Life of Gulian Eyre, according to the least blasé of magazine fashions.

Instead of the poor boy working up to his final triumph and hand of the heiress, we have a rich man, going to work. And he doesn't marry an heiress in the end or retrieve the family fortunes. He will probably have to slave to make ends meet. His former butterfly life is over, and, we draw a sigh of pleasure, for it is well told, he is glad.

The writer unfolds a thoroughly sympathetic story—almost a successful plea for the leisure class. At least he makes it seem plausible for a young New York aristocrat to get to work and become human. There are many pleasant flashes through the book, aptnesses of expression that bear rereading. Burt sees and feels, and he is honest with himself.

If there is any fault to find it is that the hero is a little too much the ideal writer. When we see the Gulian Eyres in real life we suffer disillusion. Some have such prominent Adam's apples, others affect monstrous baggy clothes, still others are weedy and affected. Gulian Eyre has the sleek exterior of a matinee idol. It comes with something of a shock to find him in business and at the same time courting beauty successfully with his pen.

Medicoliterary Notes.

The revolving stage, first brought to perfection by German theatrical architects, has been put to use to help solve the housing problem in Germany, the *Living Age* tells us. Houses of this type consist principally of one large room, one side of which is occupied by a circular revolving platform. This platform is divided into three sections by partitions radiating from the center. One of these compartments is furnished like a living room, another like a dining room, and the third like a bedroom. Other necessaries are in the large general room in one end of which the platform is located. The occupant, we can picture, gets out of bed, steps off the platform, presses a button, and his bedroom disappears and the dining room appears. After breakfast, he again steps off the platform, presses the button, and in comes the living room. The *Living Age* adds that there is as yet no news of the fate of the man who forgets to step off the platform before pressing the button!

* * * *

A recent report on some of the rules and regulations of the government pawnshop system of France reveals some interesting and amusing data. Manuscripts of novels, plays, stories and poems are accepted on the same conditions as are watches and jewelry. The shops' experts appraise the value of these manuscripts and lend money accordingly. To accommodate owners of automobiles, should they happen to be unable to meet the high prices of gasoline, tires, etc., the government pawnshops are negotiating for the purchase of a large tract of land outside Paris for the erection of garages where financially embarrassed owners may store pawned cars. The attempt of a farmer near Boulogne to pawn a cow caused the introduction of the following regulation: "Cows are not acceptable because they come under the title of perishable goods. A cow is liable to die in the sad surroundings of a pawnshop, thus making it impossible for the government to get its money if the pawner does not repay the loan or redeem the pledge if requested. Also there would be a legal tangle if a cow should become a mother during her sojourn in a pawnshop."

* * * *

Ernest Poole's new novel, *The Avalanche,* is the love story of a young physician and a New York girl. The latter's one ambition is to build up for her husband a great success. This success proves to be "the avalanche" which in the end overwhelms their love.

* * * *

The first Pan-American Red Cross Conference was held in Buenos Aires, November 25-December 1, 1923, inclusive. A full account of the various sessions and a reprint of the resolutions passed is given in the *World's Health* for February.

* * * *

At the annual meeting of the American Public Health Association last fall in Boston, the section of public health nursing was made permanent after two years' probation.

* * * *

The total average daily consumption of water in New York City in 1922 was 707,000,000 gallons. Each resident of New York City averaged forty-three rides on the street railway lines in 1860 and 432 in 1922.—*Greater New York.*

* * * *

Probably few New Yorkers remember, if they ever knew, that a little more than one hundred years ago, Greenwich Village was one of the best health resorts of Manhattan Island. In 1803, 1805 and 1822 occurred the great yellow fever epidemics in New York, causing many individuals as well as business firms, banks, and other institutions to move from the lower part of the city to temporary headquarters "up town" or north of Canal Street, so that by the last year named, quite a settlement had been established which gradually became permanent.

* * * *

The press has recently given much attention to the Milan production of Arrigo Boito's opera, *Nerone.* The Italian papers have announced that the opera, in spite of its prodigious length, was a brilliant success. This music drama portrays the contrast between pagan Rome of the time of Nero and the simple worship of the Christians who were forced at that time to meet for the most part in the catacombs and other secret places. It is said that the stage settings are not only of extraordinary beauty but have achieved historic accuracy in every detail.

* * * *

Williamsted, Curacao, Dutch West Indies, is said to be the cleanest city in the world. It is a bit of old Holland upon a desert tropical island, and, according to the *Nation's Health,* posed for the well known pictures of Spotless Town, made famous through advertising.

* * * *

Among the cleverest and most interesting shows of the season is the *Grand Street Follies* at the Neighborhood Playhouse. The impersonations of well known men about town, and of famous actors and actresses are quite remarkable in their quality of caricature, and the various skits of the evening show not only unusual cleverness of lines but an intimate knowledge of current events and political situations.

* * * *

A London dispatch quotes from a traffic report the statement that English women are much more careful when mixing with London traffic than men are. Only one third of last year's street accidents befell women. The victims are rarely London women, and even provincial women visitors are more careful of their safety than the men.

Abstracts from Current Literature

ENDOCRINOLOGY

Effect of Thyroidectemy Upon Calcium Content of Blood Serum.—I. M. Rabinowitch (*Journal of Laboratory and Clinical Medicine,* May, 1924) reports in 114 consecutive thyroidectomies two cases of tetany. In each case the symptoms were relieved with calcium salts and the patients ultimately recovered, requiring no further medication. In neither case was parathyroid tissue found in the portion of thyroid gland removed, and in both cases the calcium content of the blood serum was lowered. It appeared reasonable to assume that in these cases the tetany was not due to the removal, but to trauma of the parathyroid glands from manipulation, or temporary interference with the blood supply. This possibility was investigated. Twenty-six unselected cases in which the operation included polar ligation, unilateral lobectomy, bilateral lobectomy, and subtotal thyroidectomy, were studied. Fifty-seven per cent. of these showed a decrease in the calcium value.

Gumma of the Thyroid.—C. Williams and B. Steinberg (*Surgery, Gynecology, and Obstetrics,* June, 1924) present the following conclusions: 1. Gumma of the thyroid is a rare lesion of syphilis. 2. Women are affected more frequently than men. 3. It may result from both hereditary and acquired syphilis. 4. The symptoms are those of mechanical interference from the tumor. As a rule there is no disturbance of thyroid function. When present, it is usually myxedema, rarely hyperthyroidism. 5. The prognosis with active treatment is good. 6. The appearance of the tumor may lead to confusion with cancer.

Differential Diagnosis of Thyroid Diseases.—W. M. Boothby (*Annals of Surgery,* November, 1923) discusses the importance of correct differential diagnosis in surgery of the thyroid gland in particular, as it affects four kinds of thyroid disease, namely, diffuse colloid goitre, adenomatous goitre without hyperthyroidism, adenomatous goitre with hyperthyroidism, and exophthalmic goitre. Among the points which he brings out are the following:

Diffuse colloid goitre is a symmetric enlargement of the thyroid gland, characterized pathologically by an excess of colloid in the acini, and unassociated with symptoms of hyperthyroidism. On palpation the gland feels quite similar to that in typical exophthalmic goitre, and therefore, if the enlargement ocurs in a nervous unstable person who has symptoms recognized as "effort syndrome" or "disordered action of the heart," a mistaken diagnosis of exophthalmic goitre is readily and unwittingly made. The basal metabolic rate is a great help in distinguishing these cases from exophthalmic goitre, because the rate is not only not persistently elevated in diffuse colloid goitre, but is usually somewhat below normal, while in exophthalmic goitre, with rare exceptions, it is more than twenty per cent. above normal. Operation is indicated only if the goitre becomes excessively large and does not respond to medication; such failure of medication indicates that the enlargement may be due to colloid adenomatous tissue, and not to typical diffuse colloid goitre.

Patients with diffuse colloid goitre are safe operative risks; they also get well under medical treatment; therefore, the surgeon, by including the condition in the classification of exophthalmic goitre, will greatly reduce his mortality rate, and similarly the internist will increase the number of patients getting well under medical treatment. At the Mayo Clinic, no patient with diffuse colloid goitre and a normal basal metabolic rate has been operated on during 1922.

Adenomatous goitre masses, as a rule, do not respond completely to thyroid or iodine medication; in fact, iodine is particularly dangerous in cases of long standing of adenomatous goitre without hyperthyroidism, because the iodine is likely to stimulate, or rather aid the adenomatous tissue to hyperfunction.

Operation is indicated for adenomatous goitre without hyperthyroidism for cosmetic reasons, for the relief of pressure symptoms, and as a preventive measure against future hyperthyroidism. In order to estimate the probable risk to the patient, accurate distinction must be made between it and adenomatous goitre with hyperthyroidism. For this purpose the basal metabolic rate is of great help, because if it is within normal limits it excludes hyperthyroidism.

Adenomatous goitre with hyperthyroidism is a constitutional disease due to the presence in the thyroid gland of adenomatous tissue.

From the surgical viewpoint, the fact that the constitutional symptoms are due to the activity of the tumor is very important, because it permits the surgeon to assure the patient, before operation, of almost certain cure, provided the disease has not lasted long enough to produce permanent and irreparable damage of the heart or other organs. The operative risk is, however, much greater than in cases of adenomatous goitre without hyperthyroidism, and may be higher than in cases of exophthalmic goitre.

Exophthalmic goitre is a constitutional disease, apparently due to excessive, probably abnormal, secretion of an enlarged thyroid gland with pathologically diffuse, parenchymatous hypertrophy and hyperplasia. The condition is characterized by an increased basal metabolic rate and the resulting secondary manifestations, by a peculiar nervous syndrome, and, usually, by exophthalmos with a tendency to gastrointestinal crisis of vomiting and diarrhea. The cause of the altered pathology and disturbed function of the thyroid gland is not known.

In reply to the question: "If both exophthalmic goitre and adenomatous goitre with hyperthyroidism are due to an excess of thyroid secretion, can there be a differentiation into two diseases?" several hypothetical answers are possible, but the one held by Plummer as the most probable is briefly as follows:

The symptoms of adenomatous goitre with hyperthyroidism can be produced by the administration of an excess of thyroid extract or thyroxin; therefore, adenomatous goitre with hyperthyroidism is regarded as due to the presence in the body of an excess of normal thyroid secretion.

The symptoms of exophthalmic goitre, however, cannot in their entirety be produced by thyroid feeding. The symptoms which are not produced in characteristic form are exophthalmos, the typical gastrointestinal crisis, the peculiar nervous phenomena, and finally the metabolic status, as a result of which a postoperative reaction may arise which terminates in death within about thirty-six hours.

All of these symptoms which are characteristic of exophthalmic goitre can probably be explained on the assumption that the secretion of the thyroid gland is not only present in excess, but that it is also an abnormal product.

Certain Aspects of the Goitre Problem.—G. W. Crile (*International Journal of Medicine and Surgery,* April, 1924): Since the essential principle of the thyroid secretion is iodine and since it has been proved experimentally and clinically that the administration of iodine can produce the characteristic symptoms of a hyperthyroidism, it follows: 1, that if there is a functional deficiency iodine should be given either in the form produced by the gland itself—thyroid extract or thyroxin, or in a salt of iodine—sodium or ferrous iodide, except in cases of adenomata; and, 2, that if there is an excess of the thyroid secretion, the thyroid activity should be diminished by control and by excision of one or both lobes of the gland, according to the indications in the individual case.

The preferred treatment of patients with hyperthyroidism may be outlined as follows:

1. From the moment at which the patient is presented at the office he is subjected to a direct personal and environmental control, that is, every contact with the surgeon, with assistants, with nurses, with attendants, from the moment of his preliminary examination to the beginning of his hospital treatment, is made as free from excitation as is possible.

2. Upon his entrance to the hospital, methods for the restoration of the exhausted cells are inaugurated, that is, fluids are urged; complete rest is induced by sedatives if required; the myocardium is strengthened by digitalization, and if the condition of the patient demands it, a transfusion of blood is given.

3. The operation is performed in the patient's room and the extent of each stage in the operation is controlled by the condition of the patient. In practically all cases the operation is divided into two stages and often into three, namely, ligation of one pole, the ligation of the other pole,

he thyroidectomy. If during the surgical procedure it becomes apparent that the patient's condition is becoming aggravated, the operation is stopped at the moment, the wound packed with gauze and the patient left until his condition justifies the completion of the operation.

4. The anesthetic is always nitrous oxid oxygen and the degree of anesthesia is never allowed to pass beyond the stage of analgesia except momentarily when an especially painful moment is foreseen.

5. The postoperative treatment duplicates the preöperative regimen—rest secured by sedatives if necessary; abundant water; control of the heart; transfusion if indicated.

Clinical and Röntgenologic Study of Hypophyseal and Cerebral Obesity and Genital Atrophy.—W. Raab (*Wiener Archiv. für Innere Medizin,* March 10, 1924) states that the syndrome of dyastrophia adiposogenitalis is not absolutely fixed. Its chief elements, obesity and genital atrophy, or hypoplasia, may appear in varying degrees or entirely isolated. In the majority of cases it develops during infancy. The kinds of etiologic diseases varies for children and adults (in children more often hydrocephalus, in adults more often tumors). The hypophysis plays an important part in the genesis of the disease picture. The functionally affected part of the hypophysis appear to be the middle lobe (the site of production for the internal secretion), the posterior lobe, and the pedicle (secretory passages). The hormone of the hypophysis seems to have a regulating influence upon the metabolic and genitotrophic centres lying in the floor of the midbrain. Tumors and other processes within the hypophysis, that lead to an injury of the middle and posterior lobes, produce the partial or complete disease picture of dystrophia adiposogenitalis. The tumors arising in the anterior lobe in acromegaly affect the other parts relatively slightly; they lead mostly to genital disturbances and to obesity only when they exert pressure upon the floor of the third ventricle. Recovery follows either an artificial or spontaneous diminution of the volume of the tumor. A relationship between the pure disease picture of adiposogenital dystrophy, on the one hand, and dwarfism and gigantism, on the other, is not absolutely necessary at the begining of the disease during adolescence and can be explained only indirectly by a simultaneous disturbance of the anterior lobe either after a diminished (hypoplasia, destruction) or increased function (adenoma, irritation by adjacent processes) of the glandular portion of the hypophysis; gigantism is explainable in addition by an early secondary insufficiency of the genital glands. The syndrome may also appear independently of the hypophysis through a direct lesion of the trophic centres lying on the floor of the third ventricle, namely, through encephalitic foci, immediately adjacent tumors which crush or destroy the centres (especially tumors of the hypophyseal duct), tuberculosis of the base of the brain, gummas and also trauma, and finally through congenital malformations. Every type of internal hydrocephalus may produce the syndrome by congestion from brain tumors or inflammatory hydrocephalus, namely, by pressure upon the hypophysis, by constriction of the secretory tracts running in the infundibulum from the hypophysis to the base of the brain, and by crushing or tearing of the basal centres. The development of the syndrome after acute infectious diseases, especially in infancy, is usually the result of serous meningitis and subsequent stasis of the spinal fluid. Migraine and other cerebral symptoms of angioneurotic irritation are often associated with the syndrome, either as the result of the stasis or as a cause of the same. The familial-hereditary appearance may be due to congenital hypoplasia of the hypophysis, congenital predisposition to idiopathic hydrocephalus, abnormalities of the skull, and also to cerebral malformations. A previously unknown syndrome is the simultaneous and also familial occurrence of optic atrophy with pigmentary degeneration similar to retinitis pigmentosa. polydactylism. obesity. and genital hypoplasia.

The röntgenologic criteria for adiposogenital atrophy are: the stigma of the intrasellar tumor at the sella; the stigma of the suprasellar tumor at the sella, possibly visibility of the tumor itself (calcium deposits); the stigma of the internal hydrocephalus at the sella, possibly with the simultaneous demonstrability of a brain tumor and generalized intracranial increase of pressure; abnormal height, steep descent and possible plumpness of the dorsum with an otherwise normal sella, and an abnormally small sella.

The centres for genital growth and for the regulation of the metabolism of fat apparently lie more or less distant from each other in the floor of the third ventricle, namely, the former more toward the hypophysis and the latter nearer to the corpora mamillaria in the tuber cinerum. Consequently isolated lesions of the one or the other may occur under certain circumstances.

Encapsulated Adenomata of the Thyroid.—J. L. DeCourcy (*Annals of Surgery,* January, 1924) presents an illustrated case and offers the following suggestion for operating: In order to overcome the difficulty of finding adhesions when opening from above I have devised the following technic. Instead of opening the capsule at the uppermost portion of the tumor, a small opening is made at the lower portion. The capsule is then separated from the gland and hemostats placed above and below the line of incision. The incision is carried up both sides from below until the adenoma is completely enucleated. The advantages are as follows: 1. Area of adhesion formation is avoided. 2. Hemorrhage is entirely controlled. 3. Capsule does not have to be trimmed away after removal of tumor. 4. Operation can be performed very much more rapidly. 5. There is less trauma.

Diagnostic Endocrine Clinic.—W. Engelbach (*Endocrinology,* May, 1924), discussed endocrine anomalies clinically at the First Annual Meeting, January 24, 1924, of the American Association for the Study of Goitre, at Bloomington, Illinois, in seven groups: 1. bilobar insufficiency of the hypophysis, presenting four cases of juvenile adiposity and emphasizing the diagnostic significance of the distribution of fat and the necessity of early treatment to prevent disastrous disturbances in later life in the sexual system; 2. thyropituitary (posterior lobe) insufficiency, diagnosed by overweight at birth, by retardation of dental development, of walking, and of speech; 3. thyropituitary (anterior lobe) insufficiency, lacking the adiposity of group II and showing physical underdevelopment; 4. thyroid insufficiency; 5. pluriglandular insufficiency with epilepsy, where the case presented demonstrated the relationship of the internal secretions to the eyes and to the teeth, as well as to the mental makeup or nervous system; 6, anterior lobe pituitary hypersecretion, which may stimulate overgrowth of the osseous system; 7. Raynaud's disease in a woman with secondary hypothyroidism as shown by a high basal metabolic rate, in spite of which she has been gaining in weight.

Secondary Operations for Goitre.—E. G. Blair (*Endocrinology,* May, 1924) is convinced that all goitres begin as colloid goitres. Proliferative forms are hyperplastic and therefore accompanied by at least some hyperthyroidism. One form of hyperplasia is always associated with exopthalmic goitre. With degeneration there seems to be formed an altered secretion extremely toxic to the heart and nervous system, and especially in old adenomatous colloid goitres. The author finds that secondary operation can be successfully performed, and should be performed when, if possible before, continued degeneration of tissue left at the earlier operation causes signs of thyrotoxicosis to appear. Three interesting cases of secondary total excision are related and it is shown that function may be maintained in such persons by continued thyroid and parathyroid medication.

Adrenalin in Manual Delivery of the Placenta.—R. Joachimovits (*Wiener Klinische Wochenschrift,* May 8, 1924) before introducing his hand into the uterus pours over it a solution one fourth or one fifth of one per cent. strong of adrenalin. This causes the blood vessels in the uterine wall to contract at once. The muscular tissue does not contract, but hemorrhage ceases promptly. Consequent on the constriction of the bloodvessels bacteria are unable to enter their lumena, and all danger of blood poisoning is removed.

Treatment of Basedow's Disease with Extract of Myxedematous Goitre.—Jaquerod (*Schweizerisch Medizinische Wochenschrift,* April 17, 1924) administered goitre extract in the form of tablets, two each day, accompanied by subcutaneous injection of serum from myxedema patients, for a period of fifteen days with a month's rest and then another fifteen day period of medication. The treatment caused throbbing to cease, reduced the cardiac pulsation, diminished the size of the gland in one patient, but not in a second one, and added to weight and general condition. Exophthalmos was not affected.

Radium Therapy of Thyroid.—F. H. Hagans (*Endocrinology*, May, 1924) has treated for four years with radium every case of goitre coming under his care. This included practically every known type. Forty-five per cent. have been benefitted, more than three quarters of whom he regards as cured. Only cases with hyperthyroidism experienced improvement; to those without it this treatment may indeed prove harmful. The gland, at best, was not completely reduced to normal size, since the secretory cells are partially replaced by fibrous tissues. A reduction of two and a half inches in the circumference of the neck was the average.

The author blocks out the neck in four squares, one over each lobe, one over the isthmus, and one over the thymus. Usually one hundred milligrams of radium are used, encased in silver tubes of half a millimetre wall thickness, screened with one millimetre of brass with two or three millimetres of rubber, and mounted on a block of wood about an inch thick. This is held in position with adhesive tape for four hours over each square. Subsequent treatments are given as indicated.

Surgery of the Thyroid.—J. L. DeCourcy (*Endocrinology*, May, 1924) finds fatigue an essential factor in the production of goitre and in the occasional recurrence of hyperthyroidism after operation. When the endurance capacity is exceeded suddenly the thyroid gland becomes activated to sudden hypersecretion, resulting in hyperthyroidism. If, on the other hand, the capacity is exceeded gradually, the gland change is apt to be by a gradual increase of the cellular elements and an adenoma develops.

In advanced goitre surgery offers the most logical treatment. The author's mortality in 1498 cases has been but little over one per cent. and he finds other objections to surgical treatment minimal. The failure of surgery to effect one hundred per cent. cure in thyrotoxicosis he attributes to failure to eliminate the primary cause of the pathology as well as the pathology itself. For this reason he establishes a postoperative régime whenever possible, endeavoring to keep the patient within the normal zone of endurance and so effect a complete cure.

Action of Iodine in Goitres.—N. Jagic and G. Spengler (*Wiener klinische Wochenschrift*, January 31, 1924), report that small doses of iodine, such as three drops of five per cent. solution of sodium iodide given three times daily and gradually increased, may bring about improvement in goitres with and without thyrotoxic symptoms and in cases of exophthalmic goitres, but they may also produce symptoms or increase existing symptoms. Consequently it should be given only under careful and individual observation of the patient. The thyrotoxic effect on the heart, the first signs of which may be hyperkinetic action and tachycardia, are to be feared. Hypotonia may also act unfavorably. As a rule, the diffuse goitres are more amenable to treatment than the nodular forms. However, unusual results are not to be expected from iodine therapy even with the most careful control and individual dose in all forms of goitre. But it is a fact that recurrent nodes promptly disappear after operation.

Goitre and Mental Diseases.—H. L. Foss and J. A. Jackson (*American Journal of Medical Sciences*, May, 1924). The close observation of about eight hundred goitre cases coming to a general hospital for treatment and the simultaneous study of fifty goitre patients among seventeen hundred inmates of a large hospital for the insane, both institutions in the same locality and drawing their patients from the same territory, lead us to draw the following conclusions:

1. That goitre is not, even in a goitrous district, especially common in the insane, rather the reverse, for its incidence in the State Hospital at Danville, Pa., is but three per cent.

2 Conversely, insanity is extremely rare among the large number of goitre patients applying for treatment in a general hospital in the same locality, there being no cases of true insanity among the eight hundred patients studied, the only mental disturbance being in the form of a mild excitement or rarely slight and transient mania, this in but two cases.

3. There is, apparently, no definite relationship between goitre and insanity and surely nothing to indicate thyroidectomy in the treatment of the usual insane patient suffering from complicating goitre, unless for the relief of mechanical pressure. Operation, of course, may be indicated if there be accompanying evidences of true hyperthyroidism, but this latter condition is most rare.

4. Neither hyperthyroidism nor hypothyroidism occurs, except very rarely, among the adult goitre patients of the Pennsylvania hospitals for the insane, the greatest number of goitres being of the socalled multiple adenomatous or nodular forms and unaccompanied by systemic disturbances.

Internal Secretion of the Testis.—Kenneth M. Walker (*Lancet*, January 5, 1924), draws the following conclusions from his studies: 1. That although the testis, through the medium of its internal secretion, exerts an important influence on the development of the secondary sex characters, it acts as a stimulus to their growth rather than as the source of their origin. 2. That the other organs of internal secretion, such as the pituitary and suprarenals, exercise a control over the development of the secondary sex characters which is only of less importance than that exercised by the testicle itself. 3. That the influence exercised by the various endocrine glands on the development of the sex characters differs in different animals and in the two sexes. 4. That the internal secretion of the testis is formed not by the interstitial cells but by the cells of the tubules. 5. That the interstitial cells store up nutritive material for the use of the tubules, their function being, therefore, trophic rather than secretory.

It is obvious that these conclusions have an important bearing on the organotherapy of the testis. If the internal secretion of the testis is only one of the factors regulating the development of the secondary sex characters it is obvious that too much must not be expected of treatment by the orchitic extracts or by testicular grafts in those cases of eunuchoidism in which deficiencies in the rest of the endocrine system exist. Moreover, if the interstitial cells do not form the internal secretion of the testis, the observation that they increase in number after the operation of vas ligature cannot be taken as a proof that the output of sex hormone has been correspondingly increased. In other words, if the function of the interstitial cells be trophic rather than secretory, the arguments in favor of Steinach's operation fall to the ground.

The Goitre Risk and Local Anesthesia.—John Hunt (*American Journal of Surgery*, January, 1924) advises the careful keeping of the anesthesia record as a valuable aid in anticipating impending shock. He prints several such records, composite and individual, and offers the following technic for the application of local anesthesia, with illustrations:

In a total of five hundred and forty-eight surgical goitres our records show a mortality within forty-eight hours following operation, in five cases. Of the total number, one hundred and eight had ether anesthesia, with a mortality in three cases; three hundred and six had local anesthesia, mortality in one case, and one hundred and thirty-four had a combination of local with nitrous oxide and oxygen, mortality in one case. In 1921, we discontinued using ether, having been convinced that local anesthesia, or local with nitrous oxide and oxygen, are much safer in goitre surgery.

The technic of our local anesthesia is a combination of nerve block and infiltration. Only nerves supplying the field of operation are anesthetized. All injections are made prior to starting the operation.

Having in mind an intended bilateral resection, in which case both sides are treated alike, the description will be limited to one side. Selecting three points of skin perforation, preliminary intradermal injections are made with a fine needle, followed by perforating stabs with a sharp pointed cataract knife, at these points. These skin perforations prevent pain when the larger infiltrating needle is used and does away with drag on the shaft of the larger needle, which makes available the sense of touch in directing the point of the larger needle through the underlying tissues of the neck.

Point 1.—Opposite the superior border of the thyroid cartilage at the posterior border of the sternomastoid muscle, an infiltration is made, superficial to the sheath of the sternomastoid muscle. Through this area passes the main trunk of the transversalis coli nerve to supply the skin from the level of the hyoid bone down to a level about an inch above the suprasternal notch.

Point 2.—At the middle, and external to the thyroid cartilage, the needle is directed to the external posterior border of the cartilage, and an infiltration is made around the superior thyroid pole. Two nerves are anesthetized, the nerve passing from the superior cervical sympathetic ganglion to the superior pole external to the anterior branch of the superior thyroid artery, and a nerve branch from the external division of the superior laryngeal nerve, which enters the gland capsule internal to the same artery. By blocking the sympathetic nerve, less shock is produced during operation manipulation. The branch from the superior laryngeal is essentially a nerve of ordinary sensation. When the infiltration has been faulty, at this point, we have observed that much pain is caused during manipulation of the upper part of a lateral lobe.

Point 3.—Between the borders of the sternomastoid muscle, about one finger breadth above the clavicle, the needle is directed forward under the skin, to make a subcutaneous infiltration below and parallel to the intended line of incision. This anesthetizes terminal nerve branches which come to the skin from below, just above the clavicle and upper border of the sternum.

Action of Physostigmine and Pituitrin.—D. G. T. Kerr Cross (*British Medical Journal,* January 5, 1924) states that his experiments on the isolated human appendix have shown that physostigmine and pituitary extract, when used in combination, evince a more powerful stimulating effect on the intestinal movements than either of these substances used alone. In the author's experiments this treatment has not failed in a single case except in the presence of unsuspected mechanical obstruction.

Pituitary Tumor.—William Engelbach (*Medical Clinics of North America,* March, 1924) remarks that the diagnosis of hypophyseal neoplasm ordinarily is made with ease in the classical, rapidly developing tumor producing very characteristic signs. In those cases, however, in which there is no sellar deformity, the diagnosis becomes very much more difficult and requires a careful differentiation from other lesions in the neighborhood of the peduncles, occipital lobe, and cerebellar region, particularly if the general hormonic signs are not absolutely characteristic. The typical ocular changes, however, combined with the very classical general hormonic signs, even without sellar deformity, are frequently sufficient in themselves for such a diagnosis. In the majority of these cases, if the opportunity for prolonged observation is afforded, deformity in the sella sooner or later is noted. Bilateral temporal hemianopsia is not always present and is obtained only at a certain stage of the course and hence it should be awaited for the diagnosis of pituitary neoplasm. Typical sellar deformity when present is often sufficient in itself for diagnosis. Another important differential diagnostic point is the long duration of the course of the pituitary struma, especially as compared with gliomas. Differentiation from occipital tumors rests to a large extent upon competent localizing ocular signs. Fixation of the pupil, central blindness, and changes in the macula lutea are very important. Other localizing signs referable to occipital tumor, such as localized pain, tenderness, pressure upon the cerebellum, etc., are of only insignificant aid. In all classical cases in which definite deformity of the sella turcica occurs, associated with ocular signs mentioned above and intracranial pressure symptoms, the diagnosis is positive. Diffuse intracranial pressure symptoms, with general hormonic signs indicative of pituitary disorder, are hardly sufficient for a positive diagnosis, as a great many of the ordinary pituitary disorders not having a tumefaction as their etiologic cause have this combination.

The indications for treatment in these cases depend upon the progression of the tumor at the time of observation. If the tumor has become stationary, particularly with cyst of the hypophysis, there is no indication for immediate interference. On the other hand, rapidly growing tumors with progressive ocular or sellar signs and evidence of increasing intracranial pressure, surgery is indicated. Possibly one exception to this rule are the cases with an unquestionable history and positive physical and laboratory signs of syphilis. These cases might be tried for a limited length of time on specific and x ray treatment (gumma of the hypophysis). If this treatment is ineffective within six or eight weeks, surgery should be considered. In those cases of rapid progression in which operation is refused, the only other treatment is irradiation with x rays and radium. Medical treatment has practically no field in these cases, except in a minor secondary rôle in those which show hyposecretion of one or both lobes.

One Year's Work with Thyroid Disease.—Frank H. Lahey (*Boston Medical and Surgical Journal,* January 31, 1924), finds that thyroid extract is contraindicated in toxic cases and prolonged iodine feeding may convert nontoxic into toxic goitre. Hyperthyroidism does not exist in the absence of increased basal metabolism rate and cures of hyperthyroidism are not accomplished without returns of basal metabolism rate to normal, provided there are no conditions other than a thyroidism elevating it. Basal metabolism readings are of great value in neuroses simulating thyroidism, in that the true basal metabolism rate in the neurosis is normal. Basal metabolism readings uncorrelated are not a reliable guide to the number and extent of operations a patient will stand. Minus degrees of basal metabolism rate may exist in patients free from clinical evidence of myxedema, yet made subjectively better by raising the rate to normal with thyroid feeding. Multiple stage measures are life-saving procedures in severe hyperthyroidism. Thyrocardiac cases first seen in decompensation may be restored to striking cardiac capacity if it is possible by thyroidectomy to remove the intoxication and to restore the heart rate to within normal limits. The most dreaded, uncertain and uncontrollable factor in the clinic today is mediastinitis. The moderate values of röntgenotherapy are more than outweighed by its advantages. Thyroid surgery done in a general surgical clinic equipped for the care and study of these cases will show failures to cure and a mortality rate rarely over, and in most cases under, one per cent.

The Goitre Problem.—J. L. DeCourcy (*International Journal of Medicine and Surgery,* April, 1924) discussed goitre from the following four aspects:

First, rapid increase of endemic or simple goitre in the United States.

Second, iodine as a possible prophylaxis.

Third, fatigue as a cause of goitre; overwork in adults; too strenuous exercise in schools, especially among girls.

Fourth, surgery, so far the best solution for caring for advanced goitre.

He emphasizes particularly the element of fatigue, pointing out the frequency with which goitre develops as a result of increasing one's activity above the individual norm. Whether this is due to an acidosis or to a gradually increased call upon the thyroid secretion the author is not certain, but states that the most logical way of accounting for the formation of an adenoma is a compensatory increase in cells in order to make up an existing deficiency. Every person has a normal zone of endurance which is individualistic in its characteristics. This zone may be decreased or increased by various factors, either external or internal. It may be decreased or increased normally only by changes gradually induced, and has a limit. If the zone has been exceeded suddenly, then the glands, whichever they may be, are activated to sudden hypersecretion, and if the gland be a thyroid, then hyperthyroidism suddenly develops. If, on the other hand, the zone has been exceeded gradually, then changes in the gland are apt to take place by a gradual increase of cellular elements and an adenoma results. In cases of lung tuberculosis, especially in the ambulatory type, we frequently see signs of hyperthyroidism. When these patients are placed at rest for a while, these symptoms disappear. What probably happens is that the tuberculosis has narrowed the patient's zone of endurance, and when she persists in doing the work which she was able to do when well, she exceeds her zone and the thyroid gland is activated to hypersecretion.

The chief criticism of thyroid surgery is that it is not a one hundred per cent. cure in thyrotoxicosis. This is so, I believe, because operative treatment, up to the present, has not been founded upon a definite etiology. In order to effect a complete cure, therefore, it is sufficient merely to remove the pathology, but we must also in our postoperative treatment attempt to eliminate the primary cause of the pathology. The discussion of the various phases of etiology of goitre which we have given lends itself admirably to a logical postoperative régime, keeping the patient well within her normal zone of endurance, insisting upon a certain amount of relaxation and recreation, changing occupation when thought advisable, overcoming constipation, etc.

NEW YORK, WEDNESDAY, AUGUST 20, 1924

DIABETES

Effect of Insulin on the Sugar Content of Arterial and Venous Blood in Diabetes.—R. D. Lawrence (*British Medical Journal,* March 22, 1924) reports the following findings: 1. The normal postabsorptive difference in arterial and venous blood sugar, the venous being usually twenty to forty mg. less, is much reduced in diabetes. Higher venous than arterial figures may occasionally be found in severe diabetes. 2. Insulin increases the arteriovenous difference and approximates it to the normal. From this we may conclude that, whatever part the liver and other organs play, insulin acts largely in the muscles or general tissues.

Clinical Use of Insulin.—A. P. Thomson (*British Medical Journal,* March 15, 1924) states that the suitability of the patient for insulin treatment must be determined by a thorough clinical examination. There are cases of glycosuria in which death appears imminent from inevitable causes not connected with loss of sugar tolerance and which are unsuitable for this treatment. The use of insulin is imperative in cases of coma and of extreme wasting, when anesthesia and operation are necessary, in infections like pneumonia and tuberculosis and in young children. Patients with mild diabetes, whose condition can be controlled by reasonable dietary restrictions, do not require insulin. Insulin is recommended, in general, for every patient who cannot take the author's appropriate basal diet. Unintelligent patients are unsuitable for insulin treatment. Glycosuric patients must be carefully discriminated from mild diabetics. It is well to avoid insulin in some cases of high blood pressure, myocardial degeneration and nephritis, and possibly in the senile.

The general treatment includes, first of all, the education of the patient and instruction in the testing of the urine. All focal sepsis should be eradicated. Constipation should be corrected and young and nervous patients may be given bromides. The diet must be carefully regulated, mainly by trial and individualization. The essentials of the diet are: 1, tolerability according to the habits and desires of the patient; 2, sufficient caloric value—thirty to thirty-five calories to the kilogram of body weight for a man doing light work; 3, sufficient protein to maintain nitrogenous equilibrium—one to 1.5 grams of protein to the kilogram; 4, the total amount of glucose must be reduced to that which the body can utilize—the total glucose equals the carbohydrates plus 0.58 per cent. of the protein plus 0.1 per cent. of the fat; 5, the total fatty acid must not exceed the amount which can be absorbed without the production of acidosis—the fatty acid equals 0.9 per cent. of the fat plus 0.46 per cent. of the proteins. In each of the basal diets recommended, the protein is in the proportion of just over 1 gram per kilo of body weight.

If dieting alone does not control the condition, the patient should be treated in a hospital rather than at home. The proper control requires careful recording of the dose of insulin and the diet and the correlation of these factors with the observation of the urine and blood as regards sugar and acidosis. The first dose of insulin is calculated by dividing the average total number of grams of sugar excreted daily by three, which gives the number of insulin units for the daily dose—no more than twenty units total dose nor more than ten units to the single dose. The injections should be given before breakfast and before lunch if necessary. Relief from the socalled hypoglycemic crisis can immediately be obtained by the administration of sugar by mouth, or glucose intravenously. The latter is preceded by a hypodermic injection of a few minims of adrenalin.

Medicolegal Notes.

BASIS OF PHYSICIAN'S TESTIMONY AS TO PERMANENCE OF INJURIES.

The Circuit Court of Appeals, Sixth Circuit, Baltimore & Ohio R. Co. v. Mangus, 294 Fed. 761, states the general rule in personal injury cases to be that testimony by a physician as to the plaintiff's injury based on no objective appearance, but solely on plaintiff's statement as to the nature of the injuries, made in the course of an examination for the sole purpose of enabling the physician to testify, is incompetent; also, generally that an expert cannot be allowed to give his opnion based upon statements made to him by parties out of court and not under oath; and, generally, that an opinion based in any substantial degree upon subjective symptoms is inadmissible.

But a physician's testimony as to the injury and its probable permanence based on the plaintiff's statement of his history as far back to childhood as he could remember, covering his different diseases and the history of his accident, and containing no mention by the witness of plaintiff's narrative of his symptoms, and also upon a thorough examination, including blood pressure and all necessary adjuncts, to determine his condition, was not based on the history or on subjective symptoms to such an extent as to warrant an unqualified instruction to the jury to disregard it.

MALPRACTICE—EXCESSIVE VERDICT.

In an action for malpractice in rebreaking and resetting the bones of plaintiff's leg, which had not healed satisfactorily after a fracture, it was claimed that the defendant's alleged negligence resulted in two main injuries, failure of the fragments to unite and ankylosis of the ankle. The Minnesota Supreme Court held, Lorenz v. Lerche, 196 N. W. 564, that the recovery as to each must be supported by testimony of experts. In such a case the question put to a qualified expert should not call for his opinion as to whether the surgeon's treatment was proper or improper, but rather whether or not it was according to the customary and usual practice of the ordinary careful and skilled surgical practitioners of the same school in the community.

The experience of plaintiff's only expert witness was exceedingly limited, although he could qualify as such. He attributed the plaintiff's ankylosis, ulcers and the failure of the fractures to knit to defendant's neglect to open the cast when advised by the patient's complaints of severe pain and by the discoloration and coldness of the toes that circulation in some parts of the foot was impeded or stopped. The six experts for the defense, surgeons of long experience and high professional standing, differed from the opinion of plaintiff's expert. They all testified positively that pressure of the flesh below the fracture and resultant ulcers or sloughling would not prevent or retard the formation of a bony union at the fracture. Under this condition of the evidence it was held that the jury were not justified in finding that failure of the bones to knit was due to either the manner of the operation or the neglect to relieve from pressure.

The size of the verdict, $15,845, was held to indicate an award for all the consequences claimed in the complaint from the negligence, but the evidence was held so slight and doubtful as to the main bad result being caused by the defendant's negligence that, in the interest of justice, a new trial should be had, and the judgment for plaintiff was accordingly reversed.

And Now---for the Weak and Convalescent,

with the heat and humidity of the Summer months at hand, the value of a reconstructive tonic as efficient in action and as palatable and pleasant in effect as

Gray's Glycerine Tonic Comp.

(*Formula Dr. John P. Gray*)

becomes more apparent than perhaps at any other time of the year.

It is in the case of the elderly and infirm—especially those whose digestive organs are inactive and need aiding—that this tonic has shown its superiority to other restorative remedies.

Medical men who derive their greatest satisfaction from the success of the remedies they employ, will find that Gray's Glycerine Tonic Comp. will give them uniformly gratifying results as a tonic restorative when other measures prove to be uncertain and disappointing.

A liberal amount for testing the foregoing will be sent to any practitioner on request

VALENTINE'S PREPARATION
NUTRIO PERMIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

Smoke.—Every time a ton of coal is burned in the family furnace, seventeen tons of gas go up the chimney, sixteen of which are the gases of the atmosphere, either free or in combination with the elements of which the coal is formed. A little more than twelve tons are of nitrogen, which goes through the fire unchanged. Nearly four tons of oxygen are needed to burn the coal and this oxygen all goes up the flue as carbon dioxide, sulphur dioxide, and water vapor. Most of the coal, fifteen hundred pounds or so, also goes up the chimney, principally as carbon dioxide, less than one part in a hundred forming smoke.

French Use More Water.—M. Dienert, who has charge of the water supply of Paris, says that in 1911 one hundred litres of water for each person each day was commonly accepted as the minimum figure, whereas today it is set at two hundred and is constantly on the increase. He says that the war was responsible for many new sanitary measures that required more water, and the inhabitants never went back to their old ways. Figures relative to trade in soap between the United States and France do not throw any light upon the matter, for France sells twenty-five per cent. more of her own soap, and buys twenty per cent. less of ours today than in 1911.

Studying the Behavior of Malaria Mosquitoes.—Control of malaria is not always so simple as a statement of the essential facts would make it seem. . . . Variations in local conditions of mosquito breeding, in climate, in the character and distribution of populations, in occupations, in the nature of dwellings, in the presence of domestic animals, and in other factors create rather complicated problems which call for a combination of measures peculiarly adapted to each situation.

The International Health Board of the Rockefeller Foundation has been engaged in malaria control work since 1916. Special attention has been given to small towns and rural areas. . . . During 1923 special malaria investigations were carried on in the United States, Brazil, Nicaragua, Palestine, the Philippine Islands, Salvador, and Porto Rico. In connection with control measures in many parts of the United States incidental observations of importance were also made.

Drug Addiction on the Decline.—There are now probably not more than 150,000 addicts in the United States and their number is decreasing, says a report just published by the U. S. Public Health Service. This report is the result of a study of the extent and trend of drug addiction in the United States made by Dr. Lawrence Kolb and A. G. Du Mez, pharmacologist of the Public Health Service. It finds the peak of drug addiction was reached about 1900 when there may have been more than 250,000 addicts, and that the number is now steadily on the decline.

The estimate is based on the findings of numerous investigators and the report of physicians and of addiction clinics during the past 25 years. The highest estimate, made in 1915 gave a total of 269,000 victims. The lowest, based on the experience of the army draft figures, gives a total of 99,500. The former was made in the state of Tennessee and is believed to have been too high, since investigators found that there were proportionately more addicts in the South than in the North. The reasons for the conviction of the investigators that drug addiction is decreasing are given as the increasing efficacy of measures for the control of the drug trade, the prohibition of imports of smoking opium and the increasing caution exercised by physicians in prescribing habit forming drugs.

Estimates of the maximum total number of addicts are also derived from the known amount of drugs imported, and the report states: "To supply with their daily dose the large number of addicts asserted by some to be residing in this country would require enormous quantities of narcotics—quantities far in excess of those imported at the present time or during any period in the past!"

The period of the greatest importation of opium per capita was the decade ending with 1900. Assuming that all of it was used to supply addicts with either opium or morphine, the total number of victims could not have been more than 246,000. The report adds that the substitution of heroin for morphine would only increase this total by twelve per cent., and the imports of opium at present are less than one-fourth that of twenty-five years ago. The importation of smoking opium is forbidden.

As to cocaine, the report states: "The amount of cocaine produced in the world as well as that imported into the United States has always been small in comparison with opium. The number of addicts in the United States using cocaine alone, based on legitimate importation and assuming that all of the coca leaves and cocaine imported annually was used for the satisfaction of addiction, could never have been more than 18,300."

There are more addicts in prison at present compared with former years but this the investigators believe to be due to rigid enforcement of recent laws and not to any increase in addiction, since they hold that the present known importations are hardly more than the legitimate needs of medicine. Prison addicts are also thought to be due to the increase in the delinquent type of addict as compared with the normal individual who became an addict from medical use. Few cases of recent addiction, the investigators say, can be attributed to the prescribing of the drugs by physicians. Summing up, the report concludes:

"From the trend which narcotic addiction in this country has taken in recent years as a result of the attention given the problem by the medical profession and law enforcement officers, it is believed that we may confidently look forward to the time, not many years distant, when the few remaining addicts will be persons taking opium because of an incurable disease, and addict of the psychopathic, delinquent type who spend a good part of their lives in prison."

The League of Nations Interchange of Health Officers.—The International Health Board is providing the funds for a period of years to

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

meet the expenses of this interchange of health officers.

"It is not enough," says President Vincent, in reviewing the work of the Foundation for the year 1923, "that many young workers should get a part of their training in foreign lands, and thus feel the stimulus of contrasts and of generous rivalry. Older persons, already in important official positions, need experience abroad, the chance to make comparisons, to get new ideas, to meet colleagues, to feel a sense of comradeship across national frontiers. It was a happy idea of the health section of the League of Nations to establish what are termed interchanges of health officials, or international institutes, which are attended by representatives of several countries.

"Two such institutes were held during 1923. Early in the year twenty-nine health officers from Austria, Belgium, Czechoslovakia, Denmark, Finland, France, Hungary, Italy, Japan, Norway, Poland, Rumania, Russia, Sweden, the United States, and Yugoslavia assembled in London. After a preliminary study of the English system of central and local health administration the party broke up into small groups which proceeded independently to an intensive study of health conditions and organization in some large provincial city, a county, typical agricultural and industrial districts, and a large port. After three weeks in the provincial areas and another week spent in studying the special health problems of London, the group went to Austria, where a similar program was carried out.

"The other session assembled in the United States in September. Twenty-five delegates represented eighteen countries, including four which are not members of the League—Germany, Mexico, Russia, and the United States. After general sessions in New York and Washington the party was divided into sections which studied health activities in typical city and rural areas in Virginia, Alabama, North Carolina, Pennsylvania, New York, and Massachusetts. A final conference of the European delegates was held in Geneva for a review and discussion of their experience in the United States.

"The value—scientific, practical, and international—of such meetings as these is unquestionable. The by-product in friendliness and good will is by no means negligible.

"Still other migrations of scientific men took place under the Foundation's auspices during 1923. Twenty-four specialists in medicine, public health, or physical science, representing seven different nations, visited other countries than their own as guests of the Division of Medical Education, the China Medical Board, and the International Health Board. These visits varied in length from a few weeks to several months.

"A commission of six distinguished Japanese scientists—two professors of medicine, two of pathology, one parasitologist, and one surgeon—made a tour of the chief medical centres of the United States. . . . Other visitors from foreign countries included: a health official from Hungary; another from Poland; and two professors of the medical school of the University of Hongkong, appointees to new university chairs which had been endowed by the Foundation.

"From the United States, on the other hand, the Foundation sent one pathologist to Brazil, another to Siam, physicists to Chinese universities in Nanking and Tientsin, and a specialist in science teaching to the National Education Association of China. To the Peking Union Medical College went eight visiting professors; two from Johns Hopkins Medical School, two from the Harvard Medical School, and one each from Columbia University medical school, the Rockefeller Institute for Medical Research, the University of Vienna, and the Central Institute of Brain Research in Amsterdam."

Noxious Drugs.—Dr. W. M. Bayliss, professor of physiology at London University, and Dr. C. W. Salesby have sent the following letter to the public press: "In previous letters we have sought to draw attention to the existence of effective substitutes for cocaine and to the principle that the only means whereby the traffic in noxious drugs can be stopped is by international action for the restriction of their production strictly to the quantities needed for legitimate medical and surgical purposes. On March 5th a committee of experts is to meet in Geneva to prepare the program for the International Conference under the auspices of the League of Nations, in November next. The program must deal not only with the manufacture of alkaloids, but, as has been urged previously, and as urged by the American Delegation on this subject, with the growth of the opium, poppy and coca plant. We hope that Sir John Jordan, who will represent Great Britain at the meeting of experts in March, may receive the most ample and cogent instructions to support this fundamental and alone effective principle of international control of production of noxious drugs.

Results of the Quarantine Conferences.—The *Star and Herald*, the English newspaper of Panama, in its issue of March 1, 1924, comments editorially as follows:

Our esteemed colleague of *La Estrella* (a Spanish journal) has called the conference of quarantine officials that has just closed in this city, a real and practical kind of Pan-Americanism, and he is right. Pan-Americanism has been largely a theory and sweet dream expounded at dinners and seldom tested practically.

The conference of quarantine officials of our neighboring countries, together with our own eminent members of the medical profession and the medical officers of the Panama Canal, has been a real advance in Pan-Americanism. Naturally there were many theories expounded in the conference, but they were quarantine theories, and even on that score the conference was extremely practical.

Here on the Isthmus of Panama many of the theories of quarantine have been tried out actually and practically, and some of them discarded and others justified. It was refreshing to note that the spirit of the conference was liberal and the conferees seemed more inclined to lessen quarantine restrictions than to set up new and unnecessary barriers. . .

That has been the attitude of the officials of the Panama Canal, led, we believe, by that liberal and progressive officer, Dr. W. C. Rucker, to whom we are in a large sense indebted for the suggestion to President Porras to call the convention here. And we feel that Dr. Rucker has given the best of his considerable ability and energy to make the conference the unqualified success it has proven.

An Effective Remedy *for* Nervous Sleepless Patients

Neuronidia

Palatable Well-Tolerated Reliable

Allaying Restlessness and Producing Refreshing Sleep

Especially indicated in insomnia from mental strain, neurasthenia and other neuroses; also an excellent sedative in sea-sickness.

New Biological Station in Canal Zone.—The wild, virgin jungle of Barro Colorado Island, in Gatun Lake just off the steamship channel of the Panama Canal, will soon be the centre to which scientists seeking the secrets of little known animals and plants will flock. Construction of a biological station on that island has been begun by the Institution for Research in Tropical America, in which over twenty of the leading museums, societies, and universities of the United States are co-operating, Dr. A. S. Hitchcock, chairman of the executive committee of the organization, announced recently at the Smithsonian Institution in Washington.

The island was created by the formation of Gatun Lake in the building of the Panama Canal. It was one of the high spots in the tropical jungle which was submerged to make the lake, and contains over three thousand acres. As the waters arose in the lake, the forest animals took refuge on it in unusual numbers. Many jaguars, tapirs, and other large animals are known to exist on Barro Colorado, which is also an insect paradise and extremely rich in plant material.

Last June the government set the island aside as a reservation for biological research. No hunting, tree cutting, or settlement is allowed on it. The Institution for Research in Tropical America has been given custody of it and is now proceeding to erect a laboratory, where biologists, entomologists, zoologists, and botanists may find shelter for their apparatus and a place to set up their cots. James Zetek, of the United States Department of Agriculture, is serving as the local custodian of the station.

Barro Colorado is only a mile and a half from Frijoles Station on the Panama Railway ten miles from Gatun and ten miles from Gamboa. But although easy of access, the scientists working at the laboratory will literally have the wild at their door. Within a few feet of the station now under construction there is abundance of unstudied plants, animals, and insects. The building will be screened and protected against the wood eating ants which abound in the tropics.

Not only has this government recognized the importance of Panama as a field for biological study, Dr. Hitchcock said, but the Republic of Panama also recently set aside a beautiful site for a Marine Biological Station on the bay front in the modern section of the City of Panama, next to the site of the Gorgas Memorial.

The Institution for Research in Tropical America operating the Barro Colorado site was initiated by the National Research Council and is an association including representatives of the American Anthropological Association, American Museum of Natural History, American Phytopathological Society, American Society of Agronomy, Brooklyn Botanical Garden, California Academy of Sciences, Carnegie Museum, Commercial Museum of Philadelphia, Ecological Society of America, Harvard University, Indiana University, Johns Hopkins University, National Geographic Society, New York Academy of Sciences, New York Zoological Society, University of Michigan, Philadelphia Academy of Sciences, Smithsonian Institution, Yale University, University of Florida, American Genetic Association, and the National Research Council.

Our Northern Chronic Dysenteries

*Their Etiology, Diagnosis and Treatment**

WALTER A. BASTEDO, M.D.,
New York

In a case of chronic diarrhea a history of blood and mucus in the stools suggests dysentery, but we do not know its real nature until further study. Should the patient come from a southern country we make a careful and repeated search for animal parasites, such as Amebæ, Giardia, Balantidium, Bilharzia and others, but in persons who have always remained North we should be equally on the alert for protozoal infections. In 1894 Stockton reported two cases of amebic dysentery from Buffalo and in 1909 Patterson reported five cases of amebic dysentery from New York and found records in the literature of some fifty more cases in persons who had never been South. In the past two years we have had at St. Luke's Hospital two more such cases. Giardia dysenteries also, though usually from tropical countries, have arisen in New York, have been reported from several northern states, and during the late war occurred in considerable numbers in soldiers in the trenches and in those invalided home to England from Flanders and France. Other protozoal dysenteries in patients living North have been reported by several authors.

Bacillary dysentery also is not necessarily a southern disease, for in acute epidemics it is exceedingly common in northern countries even in winter, and it goes on to chronicity in a certain number of the cases. It is probable that if properly tested out many of our cases of chronic dysentery will prove to have their origin in such specific bacillary infection.

MICROBIOLOGY

The specific infections are caused by protozoa such as Amebæ, Giardia (lamblia) and others, by one or other strain of dysentery bacilli such as the Shiga, Flexner, Hiss-Russell and Mt. Desert, by the tubercle bacillus, the syphilis spirochete and the gonococcus. In socalled ulcerative colitis the etiological germ has seldom been determined, yet the colon bacillus, the Bacillus aerogenes capsulatus and other anaerobes, the enterococcus, the hemolytic streptococcus, strains of streptococcus viridans and possibly yeasts have proved bad actors in some cases, though all of these germs are ordinarily saprophytic and harmless and are not infrequently found in normal stools.

That the colon bacillus may produce a serious colitis was brought to our attention by Bassler in 1911, and we have had cases which we believed in this class. Others have reported cases due to Welch's bacillus, the aerogenes capsulatus. In a number of our cases the enterococcus, which is usually negative intracutaneously, reacted violently and was apparently an etiological or contributing factor. Such enterococcus dysenteries have been abundant in France and were encountered in considerable numbers in the late war. The yeasts, of special interest to us since our sprue studies (published elsewhere), have been present in abundance in some of the bad gaseous types. Davison states that the streptococci are thought to be not causative, yet this cannot be considered proved, and Herter and others believe them etiological. Undoubtedly in many cases they are more or less responsible for the seriousness of the illness and its prolongation, and this is especially true of the dysenteries caused by chemical irritants such as mercury bichloride. In one acute case resembling typhoid we found a pure culture of an unnamed streptococcus in the duodenal contents, and later this organism predominated in the stools. Weiss described an acute dysenteric outbreak apparently due to an unnamed micrococcus. If the cocci can produce acute bowel infections, it is not improbable that they can cause chronic ones.

DIAGNOSIS

During the past year the cases sent us with the diagnosis of dysentery include one of tropical sprue, two of cancer of the rectum, one of cancer of the sigmoid flexure, and two of multiple polypi of rectum and colon. We have had one case of amebic colitis in a longshoreman who has never been outside of New York city, and one case of tuberculous colitis in a lady of fifty-five years who never at any time had shown signs of active pulmonary tuberculosis. The diagnosis in the last named was based on the presence of tubercle bacilli in mucus obtained from the surface of a rectal ulcer.

To illustrate diagnostic methods we will cite a case:

*Read before the Medical Association of Central and Western New York, Syracuse, October 25, 1923.

Copyright, 1924, by A. R. Elliott Publishing Company.

Case I.—Two years ago, two weeks after an operation for appendicitis and while still in the hospital, a boy of thirteen manifested fever and diarrhea with blood and mucus in the stool. After recovery from the acute attack the loose and frequent stools continued with considerable mucus and frequently blood, but he attended school with fair regularity. When we saw him he was very thin, had a hemoglobin of 48, some colic but no noteworthy abdominal tenderness, and loose stools, two or three in the night and five or six in the daytime. His appearance suggested tuberculosis. The sigmoidoscope revealed a granular upper rectum which bled at the touch of the instrument, and the mucus obtained through the sigmoidoscope was negative for amebæ and other animal parasites and the bacillus tuberculosis. The stool was negative for ova and parasites but gave positive cultures for paratyphoid B, enterococcus, Bacillus coli communis and Bacillus coli communior. His serum, however, did not agglutinate paratyphoid B or the Shiga, Flexner, Sonne A and Sonne B types of dysentery bacillus, but it did agglutinate the Mt. Desert dysentery bacillus in all dilutions up to 1 in 320. Intracutaneous tests were likewise negative to typhoid, paratyphoid A and B, enterococcus and Bacillus coli communis; however all the dysentery bacilli strains gave decided skin reactions, that of the Mt. Desert being the most pronounced and the most prolonged. Two antiforminized stools injected each into three guineapigs did not produce tuberculous lesions. The duodenal contents were negative bacteriologically. This is apparently a case of true dysentery of the Mt. Desert type, though repeated stool cultures have not shown the Mt. Desert bacillus. In the chronic bacillary cases it is rare to obtain a positive dysentery bacillus culture, yet treatment by stock vaccines as directed by agglutination tests has proved successful. (Since this paper was written intravenous doses beginning at 20,000 of a stock Mt. Desert vaccine have been followed by great improvement, though the stools are not formed.)

METHODS OF DIAGNOSIS

The sigmoidoscope.—This instrument enables us to see lesions in the rectum or pelvic colon in almost all forms of dysentery. We have rarely seen a case of amebic, bacillary or tuberculous dysentery without rectal involvement. It will also expose a syphilitic or a gonorrheal infection, or reveal the presence of carcinoma or of papillomatous growths. In carcinoma it is characteristic that the mucous membrane is normal practically up to the projecting growth. Syphilitic lesions are not likely to be mistaken for dysenteric, but they may be indistinguishable from carcinoma and are dependent for their final determination on the positive Wassermann reaction, the examination of scrapings from the ulcer and the results of antiluetic treatment. Gonorrheal infection shows by a pus exudate corresponding in appearance with that of gonorrheal urethritis and containing gonococci.

In the ordinary types of dysentery the rectal inflammation may be nonulcerative or ulcerative. In the former the whole mucous membrane is seen to be swollen, rather dry and friable. In the latter it may show extensive ulceration with islets of mucous membrane standing out like sessile polypi, or several discrete scattered ulcers with comparatively little inflammation in the intervening areas. These ulcers are surrounded by a narrow red areola, have raised edges which are not undermined, and are covered with mucus or a yellow slough very difficult to remove. Even in amebic dysentery in our experience the rectal ulcers seem as a rule not to be undermined.

In one group the site of the lesions as revealed by the sigmoidoscope is the pelvic colon only or the pelvic colon and upper rectum, in which case there is neither tenesmus nor especial tenderness to digital examination or the insertion of the sigmoidoscope. In the other group the lesions are in the whole rectum. If the inflammation or ulceration reaches the anal canal there is tenesmus, and the instrument can be inserted only after a local anesthetic. We formerly used cocaine, but now find that we can usually depend on a five grain anesthesin suppository inserted half an hour before the examination. In hemorrhagic proctitis or proctocolitis there is free blood in the rectum and the walls bleed very freely at the touch of the instrument.

Microscopic examination and cultures.—Mucus obtained through the sigmoidoscope directly from lesions is ideal for the study of fresh or stained specimens under the microscope and for cultural study. Tissue scrapings may also be cultured. For amebæ the fresh specimens are examined on the warm stage, but for the other protozoa the warm stage is unnecessary (Davison). Tubercle bacilli show by staining methods, but since they are to be found in the stools of those with pulmonary tuberculosis it is especially necessary that they be obtained in mucus taken directly from an ulcer. For suspected tuberculosis where there are no lesions in the rectum some have antiforminized the mucus and injected guineapigs; but after the use of many guineapigs, experimenting with suspected tuberculous stools and with normal stools to which known active tuberculous sputum has been added, we have concluded that antiformin sufficient to clear the stool will kill the tubercle bacillus, therefore the method is worthless. For Bacillus aerogenes capsulatus (Welch's bacillus) we make anaerobic cultures. In chronic bacillary dysentery we seldom obtain positive cultures, though these patients react violently to one or other stock strain of dysentery bacillus when injected intracutaneously.

One may also use for microscopic study or culture the mucus from a stool or that obtained by colon irrigation after it has been washed with normal saline. When obtainable we prefer mucus rather than feces, for it is to be remembered that we are looking for an infection of the wall of the gut and not of the feces; and mucus, particularly if it is bloody, would seem in all probability to come directly from the inflamed wall.

Agglutination and intracutaneous tests.—The mere predominance of one type of germ does not determine that that is the infecting one, so that for the ultimate determination it is necessary to do agglutination tests with the patient's serum, or at least to make skin tests with vaccines prepared from the various germs isolated. For this latter purpose, having abandoned scratch dermal tests for bacterial types, we inject intracutaneously 1/100 c. c. of a one per cent. suspension of killed bacteria, this amount representing approximately 25 to 100 million dead

germs, according to the kind of germ. Agglutination tests are probably more reliable than skin tests, for it must be understood that while on the one hand the absence of a skin reaction to an autogenous vaccine is taken to mean that the disease is not due to the germ represented in the vaccine, on the other hand a positive reaction means merely that the patient is susceptible to the germ, and is not necessarily suffering from infection by it. For the dysentery tests we obtain stock vaccines of the several dysentery strains from the Department of Health. As stated by Davison, the agglutinability of living cultures has frequently been noted to vary, while that of cultures killed by formol is constant, therefore tests with the latter are more reliable.

The Röntgen ray.—This may be helpful by demonstrating the presence of a tumor such as carcinoma or hyperplastic tuberculosis. In colitis cases it shows absence of or small haustrations in the involved part of the colon, and sometimes distortion of the wall. It may reveal the site of ulceration by spasm or the rapid passage of the barium past a given spot. If the barium meal reaches the cecum in less than three hours it suggests that in all probability the ileum is also involved (Hurst), a complication that is serious.

TREATMENT

Though in the North we encounter a few chronic cases of the specific protozoan and bacillary types of dysentery, some endemic and some from southern regions, the vast majority of our northern chronic dysenteries are cases of colitis and proctitis which are for the most part unclassified etiologically. We shall therefore not linger over the specific treatment of the dysenteries due to amebæ and other protozoa, syphilis and gonorrhea.

Nor need we dwell at length on the treatment of the tuberculous dysentery cases, for as a rule they also show pulmonary tuberculosis for which they are undergoing treatment. Some of them have improved wonderfully under the application to the abdomen of heliotherapy or the rays of the Alpine lamp (Mayer), and some have seemed to improve under intravenous calcium chloride.

But for all types of chronic colitis the general treatment may be discussed at length. They may prove obstinate cases to treat, and are often thought cured when the disease is only quiescent. We may see these patients first during an acute exacerbation when they are very ill, and then they should have treatment for acute dysentery which we shall not outline here. But we see many for the first time when they are able to be up and about or have been ill for a long time, and for these primarily we should endeavor to insure adequate sleep, sufficient food and freedom from intestinal putrefactive toxemia, as otherwise they rapidly lose flesh and strength.

Vaccinotherapy.—The finding of a specific germ by culture and agglutination tests calls for the use of a vaccine. None of us feels that vaccines alone will cure a chronic case, but if by gradually increasing the resistance to the offending germ they help us to the extent of only five or ten per cent., it may be that that small percentage of assistance is just what is needed to enable the patient finally to overcome the infection. We have a feeling that perhaps vaccine reports will be better than heretofore if we limit the vaccine employed to such autogenous stool germs as give marked agglutination and skin reactions, and include all such germs in our vaccine. All vaccines should be continued for many weeks or months.

In a chronic bacillary dysentery in which the bacterial agent was recognized at the outset or the type is proved by agglutination or intracutaneous tests we may use a stock vaccine of the specific germ if we are unable to obtain an autogenous one. The vaccine is usually given subcutaneously, but in bacillary dysenteries Nolf obtained far better results from their intravenous administration. He gave doses subcutaneously till a systemic reaction was obtained, and then administered one one thousandth of this amount by vein. He gave a dose every four days with rapid increase in the amount, for example, the first dose 10,000, the next 30,000, 50,000, 100,000, 200,000 and so on. This method we have recently adopted, but because of the frequency of chills never give more than 10,000 for the first dose no matter how many can be taken subcutaneously without reaction.

Serotherapy.—In the bacillary chronic dysenteries polyvalent serum has occasionally been of great value, but as a rule it has failed to prove helpful.

Rest and activity.—Patients in a state of exhaustion and especially if losing much blood should be kept in bed, though as soon as possible they may be allowed to use the toilet, at first a commode alongside the bed. But when they are not so ill the bed is not only not necessary but is devitalizing and it is better to have them up in a sun parlor or out of doors or going about. On no account should they undertake any activity which will leave them fatigued.

Warm clothing is advisable, as a surface chill may produce exacerbation even after years. A flannel covering for the abdomen would seem to be a good addition to the clothing.

Climate.—A warm sunny climate in the winter permits the patient to be out of doors and in so far is beneficial. Hot humid climates should be avoided. Otherwise climate seems to make very little difference.

Diet.—This should be as liberal as possible, but limited in those foods, i. e., flesh and eggs, as are most likely to produce food poisoning and intestinal putrefaction, for these patients are very susceptible to such. Unless the ileum is involved the food may be well digested, so that many of these patients maintain a fair nutrition, have a good appetite and rebel against any marked dietary restrictions. If, however, there are serious digestive disturbances with anorexia the loss of flesh is rapid. For persistent anorexia lavage followed by the introduction of peptonized milk through the tube may be a good procedure.

In the Giardia, sprue and aerogenes capsulatus types there is some evidence that a high protein low carbohydrate diet is the best. But this is not true of the usual cases. The food should be in fine subdivision and not of the roughage type. Milk if well borne should form a considerable portion of it, but unfortunately in many of these cases causes severe diarrhea. We have had a number of patients who were relieved from their cramps and diarrhea by a change from a strict milk diet to heavier foods. Oc-

casionally dried or malted milk is better borne. The fermented milks, though they seem to have proved curative in children, have shown no such advantage in adults. They may be used as foods if the patient prefers them or if they agree better than raw milk. In these cases we have had no experience with acidophilus milk. Fruit even in purée form and heavy fats such as codliver oil are as a rule badly borne. Ice cold food should be avoided. When there is much loss of water in the stools water should be taken in large quantities to prevent dehydration.

For severe anemia and emaciation we rely on one or more transfusions, a treatment that may also enhance the patient's ability to overcome the infection. In addition we use iron hypodermically or by mouth, but as a rule avoid arsenic because of its possible bad effect on the bowel.

For pain our internal remedies are codeine, morphine, opium, belladonna or atropine, and benzyl benzoate. The last will check cramps if given in doses of one or two drams of the twenty per cent. solution, but its effects last only two or three hours. Abdominal hot compresses or packs, the hot water bag or hot colon irrigations are sometimes very comforting.

To check the diarrhea a simple preparation of a bismuth salt with paregoric and chalk mixture given every two to four hours is sometimes effective, or even bismuth alone. The bismuth salts are not astringent but serve as protectives to the wall of the gut. Astringents such as tannalbin and tannigen have proved very mild remedies in our hands even in very large doses frequently repeated. Codeine is sometimes helpful and is particularly effective when a nervous diarrhea accompanies the chronic state. But at times morphine or opium in considerable doses is required. The night diarrhea is the most difficult to combat and the most destructive to the patient as it causes loss of sleep. In some cases we have been able to overcome this by an anesthesin suppository or by a colon irrigation at bedtime, but sometimes it requires a large dose of opium. There are cases in which it may be unwise to check the diarrhea, but this is more true of the acute necrotic cases than of the chronic cases and we have not seen any chronic case that did not seem better when the diarrhea was held in check. As a matter of fact continued diarrhea readily saps the strength of the patient. We have tried vegetable charcoal and purified animal charcoal (℥ss) and kaolin (℥iv) without any apparent lasting good result.

To cleanse the bowels.—Some of the chronic dysentery patients are decidedly constipated and must have laxatives, such as the comparatively unirritating salines or mineral oil. But in the diarrhea cases also the repeated diarrheal movements often fail to remove their own irritating cause, and in this event much good results from an occasional cleansing cathartic dose. Some give calomel, castor oil, mineral oil or salts daily, or in small doses several times a day; but in our experience such frequent cathartic medication in a chronic diarrheal case is not only not beneficial but may seriously weaken the patient.

It is our practice to give castor oil, or occasionally calomel, once or twice a week or even less often, and we feel that it does much good. Indeed, patients themselves frequently recognize the beneficial action, and somtimes after a week or so will ask for another dose. We have repeatedly used transintestinal lavage with two per cent. sodium sulphate through a duodenal tube but have not been pleased with the results. In the cases with severe proctitis we have thought that our best results came from mouth doses of magnesium or sodium sulphate every two or three days.

TREATMENT BY RECTUM

When there is no proctitis we give cleansing irrigations of plain water or sometimes saline every day or every two or three days, or slightly astringent irrigations of silver nitrate beginning at 1-5,000 and increasing to 1-1,000. We do not believe in the introduction of irritating solutions. Even silver nitrate, 1-1,000, potassium permanganate, one grain to the pint, hydrogen peroxide or weak Dakin's solution may produce cramps. The utter impossibility of sterilizing intestinal loops has recently been shown by Dragstedt, Dragstedt and Nisbet, who placed in the loops ether, seventy per cent. alcohol, two per cent. lysol, five per cent. silver nitrate, a saturated solution of zinc chloride, five per cent. phenol, a saturated solution of salol, ten per cent. thymol in alcohol, solid camphor, menthol, naphthalin, beta-naphthol, Dakin's solution, a saturated solution of quinine sulphate, and mercuric chloride the strength of which is not stated, and failed to obtain sterilization. These remedies do more harm to the tissues of the patient than to the bacteria. The much employed argyrol is mildly antiseptic, but it is not astringent and is probably harmless. We have a new hope in the use of the acridine dyes, rivanol and acriflavine, and gentian violet. Churchman recommends acriflavine for gram negative germs and gentian violet for gram positive germs, the solution containing 1-4,000 of each. Our experience is too limited to permit a report on these dyes at present.

Better than antiseptics for the intestinal wall is probably the removal of the mucus under and in which the bacteria collect and multiply. And for this nothing would seem to surpass properly given colon irrigations with plain water using several gallons at a time, and an occasional dose of castor oil. At times we use sedative instillations of a pint or two of starch water or warm oil to be retained as long as possible. We avoid rectal injections at bedtime as they keep the patient awake.

When there is proctitis we are very careful in the introduction of tubes or instruments not to injure the mucous membrane. With a soft rubber ear syringe or a catheter and funnel we insert warm oil (℥iv) containing bismuth subcarbonate (℥iii) to be retained as long as possible, or we give small enemas of starch water. We also insert from one to three times daily a five grain anesthesin suppository. In refractory cases we insufflate calomel or equal parts of calomel and bismuth subnitrate as advocated by Soper. We have seen more harm than good from the application to rectal ulcers of silver nitrate either in stick or solution, though on occasions this may be tried in long standing cases.

SURGERY

In refractory cases surgery may be employed, the operation being for one of two purposes, namely, either to sidetrack the intestinal contents from the

diseased area, or to make an opening through which cleansing or medicated solutions may be introduced into the colon. The artificial anus to sidetrack the colon is theoretically the best operation as it keeps all food residues and feces away from the diseased colon. Yet it creates a bad odor about the patient, must be kept open a long time, and gives much trouble, consequently is used as a late resort. Therefore surgery is usually confined to an appendicostomy, or if this is impracticable, to a cecostomy, through either of which are introduced salines, antiseptics, oil, starch water, and ipecac in the amebic cases.

In sixty cases of socalled ulcerative colitis Mummery reports thirty-three patients treated medically with twenty-six deaths, and twenty-seven operated upon with only six deaths. In 1919 Logan summed up the results at the Mayo Clinic. Fifty-one patients were operated upon with an immediate mortality of 11.8 per cent. and an ultimate mortality of 27.5 per cent. Four patients later reported no improvement and twenty reported improvement. In only seven cases had the patients improved sufficiently to permit of closure of the opening within fourteen months.

The surgical literature is full of reports of success with appendicostomy or cecostomy, but because of lack of success we have resorted to it in very few cases. In our first two the operative mortality was one hundred per cent. In our next three the patients seemed to gain nothing. Since then though we hold an open mind on the question we have not advised the operation. We have treated a number in which the opening had been in daily use for from one to three years without benefit, and we have seen prompt improvement in one when the opening closed spontaneously, and in others when we had it abolished by operation. In 1919 Seale Harris said: "In amebic colitis I have had the misfortune to see a number of cases of appendicostomy done without any relief to the patient, and I did not see a single case cured by it. The operation, at one time in vogue in the South, has been largely given up." Schmidt reported thirty cases of chronic suppurative colitis, half of which were treated medically and half surgically. In the cases treated medically eight patients recovered, two died, one was improved and four unimproved. Of those treated surgically two recovered, three died, seven were improved and two unimproved. Of course the worst cases are usually the ones given over to surgery. In the hemorrhagic cases the British surgeons, Grant, Hayward, MacCarthy, Mummery and Norbury speak in glowing terms of the value of appendicostomy.

CONCLUSIONS

1. Our northern chronic dysenteries may be of any type, i. e., there is no type of dysentery that may not be met with in temperate climates, even in persons who have never been South.
2. All dysenteries should be classified etiologically.
3. The known causative germs are: the dysentery protozoa such as Amebæ and Giardia (Lamblia), the various strains of specific dysentery bacilli, the tubercle bacillus, the syphilis spirochete, the gonococcus, the colon bacillus, the Bacillus aerogenes capsulatus and the enterococcus. Streptococcus viridans and streptococcus hemolyticus strains may be etiological or may be serious secondarily infecting germs. Various anaerobes and yeasts may possibly be a cause of chronicity or of disagreeable symptoms.
4. The cases due to chemical irritants are kept chronic by secondary bacterial invasion. Other cases probably also owe their chronicity to secondary invasion.
5. Chronic dysentery is a serious disease that requires infinite patience in its treatment and persistence in care after the patient is apparently well.
6. At the present time one hope for better success in the treatment of the ordinary bacterial types would seem to lie in the use of vaccines confined to those autogenous germs that give agglutination and intracutaneous reactions, the intravenous administration being preferred. Another hope lies in the use of the antiseptic dyes, rivanol, acriflavine and gentian violet.

Prostheses in Middle Ear Deafness

W. SOHIER BRYANT, M.D.
New York

The readiest and most efficacious means of improving the hearing, in cases where there is a loss of middle ear structures, and in some cases of an impairment of hearing without loss of these structures, is the adaptation of a simple prosthesis of cotton and petrolatum. We are often so absorbed in the abstruse and complicated questions of aural technic that we do not realize the dramatic, even spectacular, quality to the instantaneous and apparently magical awakening of hearing by the insertion of a pinch of cotton in an ear that has been deaf for a life time. So unassuming is this aid that sometimes, by its very simplicity of principle, it forces us to rediscover its phenomenal value. The cotton petrolatum drum still, I am convinced, has surprises in store for us as well as for our patients. This aid can be relied on for its efficiency, since it will bring up the hearing to a working normal in a case that has lost everything except its cochlear apparatus.

INDICATIONS

A cotton petrolatum prosthesis is indicated in cases of loss of as much as half of the normal hearing efficiency due to loss or cicatrization of the middle ear structures, except in cases showing small perforations of the drum membrane, which give better results with other kinds of prostheses.

The cotton petrolatum drum is bland and nonirritating as a foreign body, therefore it has many advantages over other artificial devices. The fact

that the cotton fibre lubricated with petrolatum is less harsh than any of the other prostheses available is shown by the ease with which it is borne by middle ears, even ears with delicate and sensitive lining membranes. On the one hand, this prosthesis does not block discharge, should it occur; and on the other hand, the petrolatum prevents the formation of hard crusts.

Cotton petrolatum drums are contraindicated in cases with small perforations of the tympanic membrane; another variety of prosthesis is more efficient in these cases. Also, since in cases of active suppuration of the middle ear they make the treatment and antisepsis more difficult, they are contraindicated in these cases. There are social and intellectual contraindications, too, for we have found that stupid, negligent patients do not give the meagre but intelligent attention necessary to make the cotton petrolatum prosthesis a success. In rare cases also, some people, through the lack of necessary conveniences, have no suitable means of attending to the cotton petrolatum drums.

TECHNIC

The size of the cotton pledget is gauged to correspond to the bulk of the missing structures. If the pledget is too small, it will not stay in place, and if too large, it will muffle the hearing. As a rule, however, the efficiency of a prosthesis depends on its successful adjustment more than on its construction.

After being thoroughly saturated with petrolatum, the pledget should be placed in position by the use of forceps. The precise adjustment is a matter of patient experiment in each case, for it is necessary to ascertain the point of greatest acoustic sensibility so that the cotton may be placed on that point. (Cooperative adjustments between the doctor and the patient as to the most satisfactory position of the pledget often gives the patient a "feel" for the proper position that he sometimes becomes more expert in adjusting the cotton than the doctor.)

The determination of the proper tension required to give the best hearing results in any case requires also a great amount of experimenting.

It is necessary to replace the pledget from time to time, the forceps being used to remove the old and to replace the new pledget. In tolerant ears, the pledget should be removed before the vaseline has left the cotton to such an extent that the cotton becomes too light to perform its function, that is, usually from four to six weeks. In nontolerant ears the cotton must be changed before the ear shows signs of irritation. In irritable ears, it is advisable, before placing a fresh drum, to soak the ear for a few minutes with a saturated solution of boric acid in absolute alcohol.

Case I.—An interesting case of the rediscovery of the principle of the cotton petrolatum drum came to my attention in my office recently when a French lady came for the relief of painful and discharging ears. For many years, ever since she could remember, in spite of much medical and surgical attention, her ears had distressed her with pain and discharge, and she had always been extremely deaf. She told a revealing anecdote in her aural history. On one occasion she was inserting a wet pledget of cotton in her ear to allay her excruciating earache when, suddenly, the instant the pledget reached the bottom of her ear, she heard clearly for the first time in her life. Ever since this revelation, to keep her hearing acute, she had continued to wear wet pledgets in her ears with considerable satisfaction.

I persuaded her to undergo the distress of deafness for a few days in order to give me time to eradicate the suppuration and to allow the toughening of the mucous membrane lining of the middle ear so that they could endure the wearing of cotton petrolatum drums, which was a great improvement over the prosthesis that she had accidentally discovered for herself. (The tuning fork showed that the cochleæ of her ears were intact.)

The result in this case was that the pain ceased at once and the suppuration was stopped in both ears in six days, and three days later the patient was fitted with cotton petrolatum drums with a perfect result as far as hearing was concerned. The patient is now learning to perform her own ear toilet, changing and adjusting the drums whenever necessary.

Case II.—A deaf young woman was referred to me eighteen years ago with double chronic middle ear suppuration complicated with acute mastoiditis on one side. I performed a conservative radical mastoid operation (for the mastoiditis). The major ossicles had to be removed and the stapes was not found. The final operative result in this ear was rapid healing followed by a considerable improvement of hearing, but not enough improvement for the patient to hear ordinary conversation. After the nonoperated ear had received proper attention it soon stopped suppurating, but the hearing was reduced to a minimum, and the final result was a cicatricial condition without loss of structures or perforation of the tympanic membrane. A cotton petrolatum drum inserted in the operated ear raised the hearing to a working level. In the cicatrized ear the hearing remained extremely bad. Ten years later the application of radium to the cicatrized ear had a beneficial effect, probably loosening the cicatrices. A year after the radiation a cotton petrolatum drum placed against the drum membrane of the cicatrized ear raised the hearing satisfactorily, so that for both ears the hearing was well over the requirements of the patient's daily life, permitting her to enjoy music, theatres, church, and ordinary conversation.

Now, eighteen years after the mastoid operation, the patient reported that she wore a cotton petrolatum drum in each ear and was happy in having her hearing. During this time the patient had married and had had several children.

Every six or eight weeks she came to me to have fresh prostheses inserted. She had never acquired sufficient technical skill to do this for herself, though if the drums became displaced she was skilful at readjusting them.

There has been no suppuration of the ears since the beginning of treatment. Occasionally in hot weather, if a cotton drum is left too long in the operated ear a little irritation with serous oozing results, but this immediately dries up under boric acid insufflation. Otherwise there have been no complications in the use of the prostheses. Without a prosthesis in the operated ear the patient is annoyed by loud tinnitus on this side. Cessation of the tinnitus follows readjustment of the cotton drum.

Excess Blood Sugar in Connection with Certain Surgical Conditions*

IRA B. BARTLE, M.D.
North Bend, Oregon

Shortly after I had begun the study of the use of insulin in diabetes and making a more thorough research into blood sugar conditions in connection with that disease, at one of our staff meetings one of the members asked the question: Would it not be possible for these cases of low grade infection and wounds which were slow in healing to be carrying a high blood sugar and yet the same not show in the urine? I answered that that was possible, that it was a line in which I had made no research, and that it was a known fact that in infective conditions the blood sugar index was generally higher than in normal conditions. However, it was possible that in many cases a high blood sugar could be carried and yet not reach the threshold where it would show in the urine, and the patient be really a potential diabetic, although not a true diabetic. This led us to begin the routine examination of the blood in nearly all cases of low grade furunculosis. First, and to our surprise, we found an excess blood sugar ranging from 130 to as high as 250 or 260 or even more, and yet, in none of these cases was there any appearance of sugar in the urine. So we are not treating or talking of true diabetics, those in which at any time the sugar has appeared in the urine, because we make a routine examination of urine in all these cases, twenty-four hour specimens, twice a week, and none has ever showed even a trace.

On careful inquiry into the diet and habits of most of our furunculosis patients, we found high carbohydrate eaters, mostly among the laboring class. Their diet consisted chiefly of meat, plenty of potatoes and bread, and in many instances, was high in syrups and sugar which was used in the coffee and candy, so that we came to the conclusion that in high carbohydrate eaters there may develop an excess of blood sugar independent of a true pancreatic change. However, as to any changes in the pancreas, we of course have been unable to demonstrate that there were none. We make this presumption merely upon the fact that these patients are not diabetics and we have ample opportunity to study them, and we have studied them long enough to know that with proper care and the administration of insulin in some cases, until the error is entirely corrected, there has been no recurrence of the condition, nor has the blood sugar run excessively high when the patients have been careful in their carbohydrate intake. Most of the patients are naturally heavy eaters being engaged in hard manual labor. We found that in most cases 150 to 180 or even 200 grams of carbohydrate intake each day was common. With this great excess of carbohydrate intake it may be seen that the blood might and would carry quite an excess load, and yet, other organs of elimination being in order would not permit the overflow into the urine. In diabetic conditions any infection lowers the resistance and raises the blood sugar index. So, we might ask, would this infection raise the blood sugar index? We answer that we believe it does, but we are firmly convinced that there was an excess blood sugar prevalent prior to the acquisition of the infection, thus lowering the tissue resistance and making infection much easier and the patient much more susceptible. For instance, take a patient with a blood sugar of 150. Allow any small infection to enter the system and there is immediately started a vicious circle because infection itself raises the blood sugar on top of an already lowered tissue resistance. We would, with a patient of that sort, even in a low grade infection, probably find a blood sugar of about 170. The infections thus continue in successive crops and keep the patient in practically the same condition for months, some of our patients having had furunculosis for about two years.

In talking with Dr. McCloud, of Toronto, along this line he was of the opinion that the excess blood sugar existed prior to the infection because he pointed out that a low grade infection of moderate severity would scarcely be able to raise the blood sugar to any perceptible height, or to cause much constitutional disturbance. In some of our cases, there is much constitutional disturbance, so that often the patient is incapacitated from labor. Most of the authorities with whom I have discussed the matter are of the same opinion, that there must have been prior to infection a condition of excess blood sugar.

In many cases of severe injury, there is slow healing and a tendency to nonunion of tissue or bone. On making a routine blood examination an excess blood sugar was found in a large percentage of cases. These patients then are treated the same as the ones with the furunculosis, that is, the regulation of the diet in accordance with the case and the administration of insulin if necessary. We have, without a single exception found marked improvement after this routine has been carried out for a sufficient time to lower the blood sugar to an almost normal level. Our method of treatment for patients whose condition is not severe enough to make them stop work, is to reduce the diet to as near a 1,500 calory diabetic diet as possible, allowing a little excess intake of fats. If the excess blood sugar has been, for example, 130, as a rule a regulation of diet is all that is necessary. But in cases where the blood sugar is higher, we have administered insulin U-20 at the rate of one unit for every fifteen milligrams of blood sugar raise, or about one m. for ten milligrams raise in blood sugar. This dose is administered once a day before the noon day meal, the reason for adopting this technique is that the laborer can appear for his insulin between eleven and twelve and have his largest meal at noon, the diet being more rigidly enforced night and morning than at the meal following the insulin.

*From the Keizer Brothers Clinic. Read before the Central Willamette Medical Society, May 1, 1924.

We have found that in most cases this amount of insulin is sufficient. However, some of the cases have required a little more, say one unit for every ten milligrams of blood sugar rise. The patients in these cases, however, were more of the chronic type and yielded to treatment much less gracefully than those of the more acute type. The blood sugars are taken every ten days and in many cases ten days' treatment has been sufficient to remove the infection. The urine is taken twice a week. When the blood sugar has reached nearly a normal level, say 100 or 110 or even 120, the insulin is dropped and the patient is instructed to remain on restricted diet, the blood still being taken every ten days for twenty or thirty days. If the blood sugar then remains at normal the patient is discharged as cured.

The question probably arises: At what time are these blood tests made? All our blood tests are made during the fasting stage, generally at the morning fast, occasionally where it is impossible for the patient to appear in the morning, they are instructed to go without the night meal and appear at about 8 p. m. The fasting blood is much more accurate and stable than the evening blood, especially among the patients who are at manual labor.

CASE I.—February 3, 1924, Mr. L., aged forty-nine, came into the hospital with the first and second toes crushed so severely as to require amputation, which was done. Three or four days after the amputation the surgeon informed me that the patient was showing gangrene. I immediately examined the blood sugar and found 260. There had been no appearance of sugar in this man's urine, and it was examined every morning. He was put on a 1,000 calories diabetic diet and no fast. In three days the gangrene had extended so much, that it was necessary to amputate the foot. On the fifth day there was no change in the blood sugar. Insulin was increased to thirty-five units a day, three doses. The seventh day an improvement was noticed in the wound. This treatment was continued for two weeks when the insulin was reduced one fourth. At the present writing the wound is entirely healed and the patient much improved in general health. He is on ten units of insulin before the noonday meal and an 1,800 calories diet, no fats. This patient showed some acidosis. However, we have used no alkalines in this case except the first week.

CASE II.—Mr. J., aged thirty-eight, December 20, 1923. Severe burn from bursting of steam pipe on a donkey engine. The entire chest and arms were involved. As soon as the wound was in condition a skin graft of one hundred square inches of skin was resorted to. This graft did not appear healthy, especially along the periphery of the wound. This man's blood sugar revealed 190. He was put on 1,000 calories diabetic diet, high proteids and twenty units of insulin, in three doses. After five days the skin graft appeared to have a better color and the entire wound a better appearance. Blood sugar had dropped to 150. At the end of ten days the blood sugar was 125. Nearly all the graft had taken. Insulin was dropped and diet increased to 1,500 calories. This patient registered a complete recovery.

CASE III.—Mr. C. S., January 5, 1924, aged forty-four, longshoreman, compound comminuted fracture of the left tibia and fibula, with great loss of bony structure. Much difficulty was experienced surgically with this case in getting proper position of the bones, there being many fragments which had to be removed. A Lane plate was applied and still the tissues, being badly lacerated about the wound, did not heal properly. After six weeks we took the blood sugar and found 200. This man was put on the routine treatment with forty units of insulin daily. There was no improvement for probably two weeks, when the granulated tissue which had been giving so much trouble began to disappear and the entire wound gave the appearance of healing. To this date the man is in fine condition, a good color is shown about the wound and there is every evidence of ultimate cure.

CASE IV.—Mrs. A., aged thirty-five, April 3, 1924. Referred to me by Dr. Butler on account of a chronic furunculosis of the ear, of a severe type. This patient had been advised to have a mastoid operation, the condition in the external ear not being properly recognized. On examination we found a blood sugar of 190. The urine was loaded with sugar. This was a case of diabetes. I am reporting this case, not as one of our series but to show you the importance of these little boils in making diagnosis. This woman was put in the hospital and given one thousand calories diabetic diet, forty-five units of insulin a day and in five days the furunculosis was well under control. The blood sugar had dropped 170. The urine was sugar free. However, we tried to reduce the insulin in this case but have been unable to do so, so far. Two weeks after having seen the patient, the furunculosis was entirely gone and patient reported each day for meals at the hospital.

CASE VII.—Mr. W., May 7, 1923, aged thirty-nine, longshoreman. Appeared for treatment for successive crops of furunculosis extending over a period of eight months. These boils appeared on the extensor surface of the forearms and wrists. Did not state high carbohydrate intake but on investigation found that in the morning he floated his pancakes in syrup and was a heavy potato eater. His diet was regulated to about 1,500 calories and twelve units of insulin administered before the noonday meal. The furunculosis yielded readily in about seven days. However, in this case there was reappearance in about two weeks of greater severity than the original and a blood sugar of 170 was found. It was probably the most obstinate case we had, as each time insulin was suspended, the furunculosis appeared again. However, after a period of seven or eight weeks, we were able to discharge the patient with a normal blood sugar. I took his blood sugar last week and found it 110. There has been no recurrence.

CONCLUSIONS

The principal idea that we wish to bring home in this paper is that there is prevalent in infective cases very often a high blood sugar which can be remedied either by diet alone or by diet plus insulin, and that this fact is of inestimable value to the general practitioner whether he be a surgeon or an internist.

This study included three other cases which were omitted for lack of space.

Is Tonsillitis Merely a Symptom?*

SAMUEL M. WILSON, M.D.,
Philadelphia.

The gradual evolution of a departure from normal health into definite disease is often obscure and sometimes deceptive. This applies to tonsillitis. We usually assume that it is a disease, but I wish to offer for consideration the question whether, in becoming enlarged and extruding secretion and débris, the faucial tonsil is performing part of an important, though unrecognized, function of elimination, or whether it is a diseased condition, secondary to inflammation of the nasal mucosa or is due to a local infection. Each of these views has been advanced by men whose opinions are worthy of consideration. Is it probable that in trying to cure tonsillitis we are sacrificing organs enlarged, inflamed, or exhausted by overwork (6, 26, 25, 37, 35)? Their location in the sulci between the faucial pillars, seems adapted to permit considerable swelling without pressure necrosis.

Several years ago one of my patients became seriously ill after an uneventful operation for the complete removal of the faucial and pharyngeal tonsils. Menstruation had been normal, but ceased and was not reestablished for almost two years, and marked symptoms of neurasthenia developed. The sudden onset of such severe symptoms is unusual, but I was able to find in my records the histories of other cases in which delayed or disturbed menstruation followed tonsillectomy performed about the time of puberty. Such sequelæ would not be brought to the notice of laryngologists, so several gynecologists and internists were asked whether they had noted similar cases. They replied in the negative.

The large size of the tonsils in this patient, and the bad effect of their removal, make it appear probable that the hypertrophy had been vicarious, or to assist the function of another organ, at that time wholly or partly disabled. The question arises, however, what the use of the tonsils may be. Are they an important part of the endocrine system (15, 14, 30, 25, 22, 26, 16), and does the patient receive benefit or injury from their removal for tonsillitis (5, 16, 18, 19, 22, 23, 37)? Are they a breeding place for the germs which they always harbor, or are the latter undergoing changes there that are preliminary to lysis and the formation of immunity producing substances? Probably the most popular theory is that during infancy the tonsils assist in inducing natural immunity to the infections (11, 8, 3, 9, 18, 7, 12, 16). The opinion is often expressed that this activity ceases when the child is three or four years old, but it is not logical to assume that they then reverse their action, and favor the infections which they formerly antagonized. The operation of tonsillectomy is the removal of these glands, and when performed under a general anesthetic, the pharyngeal portion of the ring, colloquially known as the adenoids, is usually removed at the same time.

Fraenkel, Goerke, Schoenemann, von Lenhardt and others (13, 21, 33) declared tonsillitis to be secondary to infection or inflammation of the nasal mucosa, and most clinicians regard it as a local affection with constitutional symptoms. Osler (1) expressed himself as inclined to that view, although evidently feeling that the question was debatable. Teachers are accustomed to tell their pupils that a patient with acute tonsillitis is usually more seriously ill than the local condition appears to explain, and that there may be no subjective symptoms to direct attention to the tonsils during the early stages of an acute attack. The pharyngeal disturbance only would in these instances be discovered, because a painstaking general examination of a sick patient disclosed an inconspicuous lesion in his throat. If Ashhurst's views were correct, this would be merely a symptom of a general infection (6, 37).

After Wood (17) had proved that germs could enter through the tonsillar crypts, it was accepted as a fact that they frequently did so, though Wright showed (10) that live germs were usually arrested there. Hare and others (12, 16, 10) taught that the tonsils resisted such entry, unless the system was weakened by disease, or the germs virulent. That there is some relation between rheumatism and tonsillitis is beyond question, but Musser (2), among others, noted that these manifestations frequently alternated, and he found difficulty in deciding which was the primary disorder.

The popular view has been that the infecting organism of rheumatism enters through the crypts, but W. W. Ashhurst (6) observed an attack of acute tonsillitis, apparently induced by the excretion of toxins through them, and Zahorsky (18) has expressed the opinion that an attack of acute tonsillitis is, for a time, followed by increased immunity to acute infections.

We know that bacteria, pathogenic elsewhere, are normal and necessary in certain parts of the digestive tract, so that their constant presence in the tonsils proves nothing for or against these organs (9). Laboratory experiments by Ott, Farmachidis, Masini and others (14, 30, 15) have shown that the administration of tonsil extract to animals results in an increased flow of urine and has apparently an effect on the blood pressure. The congestion that is common at menstruation and during sexual activity and the troublesome bleeding that often complicates tonsillectomy performed about the time of menstruation appear to confirm the belief that they are functionally associated with the generative system. The increased bodily growth, often noted in boys after tonsillectomy, may have a similar explanation. In treating cases of cardiorenal disease with high blood pressure, I have in several instances seen considerable improvement follow the administration of small doses of tonsil extract for a couple of weeks. Secretion of urine has increased, and in some there has occurred a simultaneous diastolic rise and systolic fall toward normal, such as often takes place from the use of digitalis. This latter is not constant, but a systolic pressure, subnormal from any cause, be-

*Read before the Philadelphia County Medical Society, June 11, 1924.

comes still lower if tonsil extract be given. As the tonsils are frequently excised in the hope of overcoming persistent high pressure, this fact might deserve consideration.

Like many others, I was formerly very enthusiastic about the brilliant results that appear to follow tonsillectomy in some cases of chorea, rheumatism, and allied disorders, but these results do not always stand critical study nor the test of time (18, 27, 29, 38). Articles are becoming numerous and opinion outspoken in regard to this, pleading for care in diagnosis and more attention to the sinuses, ears, and septal deflections, before assuming that the primary trouble lies in the tonsils, even though these may appear somewhat large (29, 16, 21, 33, 13, 34, 35).

Treatment of the nose is usually required, in addition to that of the tonsils, and if well performed will, in most cases, render a tonsil operation superfluous. When the eyes, kidneys, spleen and other organs show evidence of disease, it is customary to try to restore them to normal, undertaking their excision only when such methods fail. As the tonsils usually respond readily to conservative treatment (19, 26, 23), why should we not make use of it?

Pulmonary abscess and acute tuberculosis are not uncommon after tonsillectomy, and have usually been attributed to prolonged or unskillful anesthesia or to the inspiration of pus. The dexterity and experience of some of the operators concerned would lead to great doubt about this explanation, and it seems at least plausible, as has been suggested (28, 31, 20, 36), to attribute it to infection through the blood by emboli, the operation *per se*. Perhaps it may also be the loss of the functioning tonsil and the consequent overwhelming of the system by an unresisted infection or to the disturbance of the endocrine chain.

Barnes and others (7, 37, 24, 16) have drawn attention to the hypertrophy of adjacent lymphoid elements after removal of the faucial and pharyngeal members of the ring. Barnes and Mackenzie state that this is normal and vicarious, meaning apparently that they develop to secure the performance of the function of the ablated organs. Richardson thinks it a pathological recurrence. In patients with high blood pressure, compensatory hypertrophy of the lingual tonsil may be great enough to cause obstructive symptoms, although it may appear to be healthy tissue.

None of these observations carries proof of useful function, but taken collectively, they are suggestive of there being such, and from a clinical viewpoint this is important, as it might materially alter our views about the appropriate treatment.

CONCLUSIONS

We do not yet know whether the tonsil is an important part of the organism of an adult, and tonsillitis is usually an incomplete diagnosis. A cause for it can in most instances be found, and cause and effect are together relieved by appropriate treatment. Like all operative procedures, tonsillectomy has its place, but it is not a general cureall for toxemia. It should only be performed when necessary, after a careful, discriminating diagnosis; not with the thought that it is harmless, whether it helps or not.

The author's references will appear in his reprints.

Problems in Eclampsia*

IRVING SMILEY, M.D.,
New York.

To correlate and discuss the many theories placed before the medical profession in the study of eclampsia would be too time consuming and of doubtful benefit. Suffice it to say that while much has been done a great deal more remains to be done before a definite etiological factor will be found in the causation of this condition. The fact that eclampsia causes more deaths in childbirth than any other disease, except sepsis, is sufficient excuse to bring the subject again and again before the profession in the hope that still more study and further effort will be expended in prophylaxis of this disease. While it is true that many cases of eclampsia are fatal from the very beginning of the condition in spite of any and every form of treatment, it is also true that at least eighty per cent. of all cases can be avoided by a proper study of the prenatal conditions always found in these patients. The reward to be gained by watchfulness and care is of sufficient importance to call attention again and again to the salient features of eclampsia as we know them today. However, a short résumé of some of the important theories in connection with eclampsia will be in place, since it may help to elucidate the different methods of treatment as practised at present.

*From the Department of Obstetrics and Gynecology, Bronx Hospital.

THE KIDNEY AS THE DISTURBING ELEMENT

For a long time it was supposed that the kidney was the primary organ affected and that eclampsia, like uremia, had its origin here. In fact, eclampsia and uremia were supposed to be one and the same thing, and added to the clinical similarity was the finding of pathological changes in the kidneys of patients who came to the autopsy table. However, enough is known at present to show that the pathological changes in the kidneys are not entirely similar, and that the clinical features differ to a great extent. The entire question is still surrounded with doubt and mystery, and investigators are seeking light as to whether the changes in the kidneys are secondary to other pathology, as in all toxic conditions, or whether the changes found are due to pressure by an enlarging uterus upon the kidney or ureter, with consequent disturbance of the circulation. The consensus of opinion now seems to be that the kidney is affected secondarily, or that there may

be two forms of eclampsia, one known as the renal type, in which the kidney is the primary seat of disease and the liver the secondary, and the second known as the hepatic type, in which there is secondary involvement of the kidneys. That there is a true kidney of pregnancy cannot be denied, but exactly what rôle this plays in eclampsia is by no means definite.

THE PLACENTA AS THE CAUSE.

Since 1901 when Cocchi found that injections of placental substances caused lesions of the kidney and liver, the placental theory seems to have gained considerable ground. Those working along this line of investigation assume that the physiological syncytiolysis is the fundamental process which makes eclampsia possible. Importance has been added to this theory by the discovery of hormones in the placenta, so that the placenta has been given the rôle of a ductless gland. That there is a definite hormone secreted by the chorionic elements of the placenta is definitely certain, but just what effect it has upon the maternal organism is not yet known.

Secondary factors comprise the presence in the blood serum of a substance which activates this placental enzyme or toxin, and the absence of some inactivating material which normally protects the organism. The theory of anaphylaxis rather upholds this view, for the mechanism involved in sensibilizing the gravida to a poisonous principle presupposes the absence of some immune body. But while the reaction of the gravida toward the absorbed placental villi is a fact, and valuable as it goes, it does not by any means account for eclampsia as a whole. Some observers have described a ferment present in the placenta, similar to that in the pancreas, which ferment is able to split up the albumin in the maternal organism. Pathological changes here cause the trouble.

Veit holds that the process is due to the presence of placental cells in the circulation, while Ascoli asserts that these cells in themselves are not toxic, but when dissolved in the maternal circulation become toxic. If the organism produces antitoxins, all goes well. Halban makes the unequivocal statement that all maternal reactions are due to an internal secretion of the placenta. The recent work by Titus and Givens, whereby they try to prove that in eclampsia there seems to be a shortage of carbohydrates in the maternal organism, due to an unusual demand on the part of the growing fetus, with a consequent depletion of glycogen in the liver, may be linked up with the effect of the placental hormone in the liver. The whole phase of the placental theory is clouded by such uncertainty that it is impossible to arrive at any definite conclusion.

INTERNAL GLAND THEORY.

This phase of the subject is coming more and more to the front at present due to the interest shown in the study of ductless glands. The thyroid naturally bears the brunt of the guilt for various reasons. A slight enlargement and hyperactivity of this gland is physiological in pregnancy. This hyperactivity may take place with no appreciable change in size, and is essential in order that the increased metabolism consequent upon the pregnant state can be taken care of. Failure of the thyroid to accommodate itself, either through hypoactivity or hyperactivity, leads to an unbalancing of maternal anabolism and catabolism, and a toxic state ensues. Since the thyroid itself seldom plays a lone hand, it is natural to suppose that other glands take part in the process. The effect of the corpus luteum secretion, which is supposed to be stored up in the placenta, is unknown. The pancreas, adrenals, pituitary, etc., share in the pathology, and, here again, the glycogenic function of the liver may be disturbed.

TYPES OF ECLAMPSIA

Two types of eclampsia have been recognized from an endocrinological viewpoint, cases with thyroid hypoactivity and an insufficient secretion to take care of the increased metabolism in the liver, and cases associated with Graves's disease, which condition is made distinctly worse by pregnancy. Hyperactivity of the parathyroids leading to a rapid withdrawal of calcium from the maternal organism has also been spoken of as part of the process.

THE FETUS ITSELF.

The view that eclampsia is due to fetal products, toxic in nature, circulating in the maternal circulation, is feasible at its face value, but indefinite and lacking confirmation upon close investigation. Nothing can be found in the blood or urine of the mother that can be regarded as toxic material. The nitrogen, which the fetus absorbs, is burned up to the physiological product, urea, by the oxygen transported to it by the placenta, and only minimal amounts of urea and creatinin pass into the maternal organism. In the most unfavorable cases, if the kidney of the fetus should not secrete at all in twenty-four hours, only 1.4 grams of urea would pass into the maternal organism. With a body weight of 175 pounds the adult can produce thirty-five grams of urea—a fetus of seven and a half pounds produces about 1.4 grams (studies of Blumreich). This increase of thirty-five grams to 36.4 grams is the limit of the increase of physiological fluctuation, and can also be achieved by the mother by an increase in her diet of fifty grams of meat a day. Also, the claim that this fetal refuse goes directly into the vena cava cannot hold, since the same thing happens continually in maternal metabolism, the only exception being the intestinal products which go by way of the liver. This theory also fails to account for cases of eclampsia where no fetus is present, as in moles.

THEORIES OF TITUS AND GIVENS.

The work of Titus and Givens as mentioned above may be a step forward in the right direction, if their work proves to be accurate and confirmed by other observers. According to them the reserve store of glycogen in the liver is drawn upon, with the result that a depletion in this organ occurs. Pathological changes in the cells result from this depletion, and its detoxicating and other normal functions are primarily impaired. The disturbances in the kidney functions are probably secondary to hepatic changes. Perhaps, as stated above, the ductless glands, including the placenta, may take part in this depletion process. They lay claim to favorable results with their method of treatment, but claims of all sort have been put forth only to fall by the wayside and lie forgotten in the medical graveyard.

VASCULAR TONUS.

Much work is being done at present upon the cause and effect of increased vascular tonus or angiospasm, which affects the entire peripheral circulation. Little can be said positively about this phase of the problem at present, and reports are meagre and require substantiation. It may be possible that the toxins circulating in the maternal blood produce a pathological effect upon the capillary system, with the consequent changes in the kidneys, liver, brain, etc., and may, in fact, account for the edema in the various parts of the body. Nevertheless, it cannot and does not explain anything relating to the causation of the disease itself. Delay in capillary current with stagnation alternating with good current is due to spasms in the precapillary vessels.

LABORATORY AND RESEARCH WORK.

A tremendous amount of labor has been expended in laboratory and research work, but little light has been thrown on the subject. The conclusions of Slemons in his *Analysis of the Blood in Eclampsia and Allied Conditions,* give a fair estimate of just what is to be expected at present from this branch of research work. There is the usual quantity of aminoacid and a slight retention of nitrogenous waste products, as urea and uric acid. After convulsions there is a slight increase in the blood sugar. The total fat is approximately the same in cases of toxemia as in normal pregnancy. Usually the cholesterol is increased and the lecithin diminished in eclampsia. The carbon dioxide combining power of the plasma is residual during normal pregnancy, indicating a mild acidosis, and the variations met with in the presence of autointoxications are insignificant. These results do not support the acidosis nor the derangement of protein metabolism theories of eclampsia, and indicate that the cause of the disease must be sought elsewhere.

Naturally, the urine has come in for a great deal of attention, since often it gives the first manifestations of trouble. Abnormal findings in the urine are more or less constant in almost ninety per cent. of the cases. In ten per cent. careful examinations of the urine in eclampsia have been entirely negative. Many cases show the presence of urobilin and urobilinogen, which may indicate early hepatic irritation. The study of the urea output shows little, and Cragin has shown cases with marked low urea output and no symptoms following.

The presence of urobilin and urobilinogen in some cases and not in others has further strengthened the conception of renal eclampsia and hepatic eclampsia. It is doubtful in my mind whether such a classification has a positive leg to stand on. Imagination has to be stretched considerably to suppose that the presence of a toxin in the blood, evidently the same in all cases and produced from the same sources, will produce in one case degeneration of the kidney tissue, and in another case skip the kidney and damage the liver. I am inclined to the view that there is in all cases a definite selective action of the toxin in the liver primarily, and that the changes in the kidney parenchyma are secondary following the rôle played by the kidneys in all toxic conditions. I have never yet failed to find at an autopsy of an eclamptic patient definite gross and microscopical changes in liver tissues at all stages of degeneration, even up to massive necrosis. Definite changes are also found in the kidneys, but not as severe as those in the liver. Our attention is always called to the kidneys because often the first sign of trouble is discovered there, and the picture of kidney involvement is usually the predominant one the patient presents. Many pregnant women give definite signs of the pregnancy kidneys with albumin, casts, edema, etc., with absolutely no sign of a toxicosis.

A bit more about the pathological changes found in eclampsia. Fahr's latest contribution gives the following after a careful study. The changes in the glomerulus of the kidney consist chiefly in diffusion and tumescence of the capillary wall, varying in intensity and degeneration of the nucleus. The vessels show focal thickening and swelling of the walls of the arterioles. The capillaries show unsymmetrical filling and stasis. Hemoglobin casts may be present. The eclamptic liver in mild cases shows congestion and fatty degeneration; in the severer cases large hemorrhagic and anemic necrosis; microscopically, in the periphery of the lobules there are localized fibrin thrombi; in the capillaries of the portal vein, stagnation followed by cell destruction and independent degeneration in the form of hyalinization and fatty degeneration. The stasis, hemorrhage, and necrosis are caused to a great extent by thrombus formation through the eclampsia toxin which produces coagulation, but there is without doubt also a direct toxic action in the vessel walls and liver cells. It is possible that the vessel spasm may help to cause the liver changes, this spasm being indicated by a premonitory rise in blood pressure in eclampsia, and by direct observation of the capillary changes dependent on thrombosis which are more pronounced in the liver than in the kidneys, because the toxin passes through the hemorrhoidal veins directly into the portal vein, and occlusion of the small branches of the portal vein makes it impossible for the blood to flow freely, with resultant stasis and hemorrhage in the arterial capillary region. The liver receives the coagulating substance at first hand through a vein in which coagulation develops more readily than in the arterial tract, because of the slower current. There may be no relationship between the extent of the necrotic processes in the liver and the severity or number of convulsions.

STAGES OF ECLAMPSIA.

Eclampsia for the sake of clearness and brevity may be divided into the three following periods, 1, the prodromal stage; 2, the preeclamptic stage; and 3, the true eclampsia, which may be subdivided into mild and severe eclampsia. In the treatment of these stages the preeclamptic and mild eclampsia may be classed as one.

The prodromal stage.—Recognizing the condition and treating the patient vigorously at this time is to my mind the most important element in this situation. The first symptoms manifest themselves in the later months of pregnancy, usually from the sixth month on, and in about seventy-five per cent. of the cases occur in primiparæ. These symptoms may be so slight and so often resemble the harmless mechanical results of pressure of the large heavy uterus, such as indigestion or constipation, that only by careful

watching will one be able to detect the passing of the physiological into the pathological. Among the earliest symptoms complained of are a tendency to insomnia, more or less irritability, inability to keep one's mind concentrated upon one subject for any length of time, slight headaches, followed by a resumption of the vomiting. The patient complains bitterly of being uncomfortable; edema may or may not be present at this time. Examination of the urine will disclose traces of albumin, a few hyaline casts, perhaps a lowered urea output, possibly a faint trace of urobilin and urobilinogen. The blood pressure may show a gradual rise above 130 systolic; in fact, this rise in the blood pressure may be the first signal to call attention to the fact that all is not well.

At this stage, if treatment is vigorous and careful, the entire course of the disease may be stopped short and further complications avoided. This holds true in about eighty per cent. of the cases, the other twenty per cent. passing quickly into the preeclamptic state in spite of all effort and treatment. The symptoms here become more marked and the clinical picture becomes more ominous. The headaches become more intense, various disturbances in sight take place, and there is epigastric pain accompanied by vomiting, often a grave sign of impending danger. The urine becomes scanty in amount, albumin is increased, hyaline and granular casts present, and the edema is more prominent. The blood pressure shows a steady rise and may be from 150 systolic up. The study of the blood pressure has become more common and its importance is being more and more emphasized. Williams ascribes it to the constricting property on the arterioles of the eclamptic toxin with a constant reduction of the lumen and an increased resistance in the arterial tree. The average blood pressure should be between 100 to 125. A steadily increasing rise in repeated examinations should immediately call attention to the fact that something is wrong, and a thorough examination be instituted and measures taken to combat further trouble. Irving's statistics are interesting. He shows that in cases where the blood pressure is 130 to 140, one in every thirty-two patients manifest toxemia; with a pressure of 140 to 150, one in eleven; with a pressure of 150 to 160, one in three; from 160 to 180, one half are toxic, and above 180, all cases become toxic. Elevated blood pressure may be the first sign noticed, and is a more frequent early symptom than albuminuria, and is not proportional to the amount of albumin present in the urine.

Even at this time much can be done to prevent the final stage—the true eclampsia. This phase of the disease is ushered in with the characteristic convulsions. It often happens that the convulsions are the first intimation the physician has that he is dealing with a toxic condition, but I cannot but feel that in these cases the patient presented preeclamptic symptoms before her convulsions took place, and that for some reason or other the constitutional disturbances went unnoticed by both patient and physician. A careful history will always bring out that the woman had been suffering from some disturbances that were not normal. The eclamptic period may be divided into two stages—the mild and severe. The differentiation between the two is often impossible, and no arbitrary rule can be laid down. In apparently mild cases the patients have died in spite of any form of treatment, and vice versa. As a general rule, however, it may be stated that the degree of severity will depend upon several factors. The amount of albumin secured from the bladder by the catheter, the number and frequency of the convulsions, and the mental condition of the patient, may give an idea as to the severity. If the urine is scant in amount and boils solid; if there have been ten or more convulsions, or if the patient is in a state of coma, such cases should be classed as severe. On the other hand, if a fair quantity of urine is obtained, the amount of albumin moderate, and especially if the patient's mental condition is clear between attacks, with long intervals between the attacks, we are justified in classing such a case as a mild one. Such a classification is of some importance when treatment is considered. In the socalled mild cases the mortality is one fifth of that of the severe cases, and also the choice of the method of treatment may be different. These cases are admirable for treatment by the conservative method, and give the splendid results reported by Stroganoff, Zweifel, and the Rotunda Hospital. The severe cases will naturally call for more radical treatment with higher mortality rates. It is for this reason that I think it important for the physician to know definitely just what sort of condition he is dealing with as far as possible. The exceptional case proves the rule and should not be sufficient cause to avoid any classification.

The time to treat eclampsia is before its occurrence. This point cannot be too often repeated, and if once thoroughly realized eighty per cent. of the cases can be avoided. The proper prenatal examinations made regularly and conscientiously will usually detect the early signs and symptoms of impending toxemia, or its presence, and the careful management of the case at this time will carry the patient to a successful termination of her pregnancy, with little or no trouble in the majority of cases. The careful interpretation of complaints, and the proper examination of the blood pressure and urine, will give the attending physician sufficient knowledge as to the progress of his patient's condition. The mere examination of the urine for the presence of albumin is not sufficient, but search should be made for casts, blood, urobilin and urobilinogen. Careful observations of the blood pressure should be made and records kept. A sudden rise or a gradual rise over a period of time should demand investigation. Eternal vigilance will bring its reward.

The treatment of the prodromal stage should be strictly enforced, and under the control of the physician. Hospital care should be instituted if this control cannot be obtained at the patient's home. The patient should be placed in bed immediately so that complete rest may be secured. A stoppage of all food, and only milk, from two to three quarts a day, allowed. It may even be necessary to stop this food. All the organs of elimination should be stimulated so that the proper functioning may take place. Daily warm baths should be given to stimulate the action of the skin. The bowels should be made to move daily, or even several times daily, and saline cathartics administered to secure these results. A daily colonic irrigation of several gallons, preferably with five per cent. glucose solution, should be given, and

upon the return of clear fluid a sufficient quantity be left in the bowel for absorption. The kidneys should be activated and may be helped by the proper use of diuretics. This course of treatment should be kept up until there is definite improvement, which usually takes place in from ten to fourteen days. As the condition improves the diet may be gradually added to, and the patient allowed out of bed. A careful watch should be kept over her continually, and if any tendency to relapse occurs, an immediate return to treatment be instituted. In this way often the patient can be carried to full term and labor proceed normally with no untoward results. Thyroid extract in five grain doses should be given, and a watch kept on the heart action, decreasing the dose if necessary. Calcium lactate may also be tried.

If, in spite of treatment at this stage, the patient grows progressively worse, which will happen, or if she is seen in the preeclamptic period, a definite routine treatment should be planned and the advisability of terminating pregnancy considered. The urine becomes scanty, edema more marked, frontal headaches persist, vomiting takes place, eye symptoms manifest themselves, and epigastric pain is complained of. There may also be present a severe itching over the body. Such a picture completes the clinical aspect of the preeclamptic, who soon lapses into convulsions.

CONSERVATIVE TREATMENT

It is at this time that the socalled conservative treatment finds its greatest usefulness. The method of treatment chosen should be one of simplicity plus the avoidance of shock and trauma as far as possible. Furthermore, the physician should not be the slave to any one method of treatment. There is not and cannot be one particular line of treatment for this condition. A definite plan should be determined, depending upon the condition of the patient, the severity of the symptoms, the period of pregnancy, and the condition of the cervix. The plan should combine the best that can be found in the Stroganoff, the Zweifel, the Rotunda, or any method that the physician thinks will bring results. The main point to be considered is to get away from the routine method of treatment, and to treat each patient individually. Fit the treatment to the patient, and not the patient to the treatment. It should be remembered always that no two eclamptic patients are exactly alike and each must be judged individually, and, I repeat, the method chosen should be the best for that particular patient, regardless of whether it is conservative or radical.

The patient should, of course, be in a hospital, preferably in a darkened room, and under continuous supervision by trained nurses. Care should be taken that the respiratory passages are clear.

An initial dose of half a grain of morphine sulphate is given hypodermically, and when its effect is noticed the stomach is washed out with a solution of bicarbonate of soda. As soon as the stomach is empty either magnesium sulphate or castor oil is passed into the stomach through the tube and left there. A high colonic irrigation of from three to five gallons of a five per cent. solution of glucose is then given, to be repeated in twelve hours if necessary, and at leat one pint of this solution is left in the rectum. With the patient now under the influence of the morphine, the blood pressure should be taken and vaginal examination made to determine the condition of the cervix, the position and presentation of the fetus. If the pressure is 175 or above, a sufficient amount of blood—usually 500 to 700 c. c.—should be withdrawn from the arm until the pressure, if possible, is brought to 150. Intravenous injections of 250 c. c. of glucose solution (50 grains to 250 c. c. of water) may be given and repeated if necessary. The patient may be wrapped in warm blankets. Wet packs should be avoided as they are too depressing. With these measures accomplished the patient is usually quiet and will have fallen into labor by this time. In multiparæ when the cervix is soft, dilated to some extent, or easily dilatable, the membrane should be ruptured, or a bag may be inserted, and labor allowed to proceed normally. As soon as full dilatation is secured, the second stage may be omitted by the proper application of a low or medium forceps. If dilatation is proceeding slowly and the patient shows signs of irritability or convulsions appear again, dilatation may be secured manually and delivery hastened by forceps. When manual dilatation is necessary it should be done slowly and carefully under complete surgical anesthesia and every means taken to avoid laceration. There is never any indication for rapid cervical dilatation, and the half hour that might be saved by rapidly dilating a cervix will be at the expense of an hour's suturing of a torn bleeding cervix after delivery, besides the great loss of blood and shock incident thereto. In these cases where labor does not start it should be induced and allowed to proceed, or hastened, in the manner described above. Version may be tried if dilatation is complete and the head still high and the measurements normal.

The same general principles of treatment can be carried out in primiparæ where labor has begun; every measure instituted should be for the purpose of hastening its end. The various means at hand to hasten the first stage, as mentioned above, such as bags, manual dilatation, etc., may be employed and the second stage terminated by version or forceps. In cases where labor has not started and conditions are favorable, that is, the cervix shows a tendency to soften, labor should be induced regardless of the period of gestation. All measures undertaken should be performed under complete surgical anesthesia.

Those cases that can be classed as of the severe type, either from the onset or those passing from the mild to the severe, will usually require a more radical plan of treatment. The preliminary treatment as outlined above should be instituted and the operative procedure be determined upon, planned according to the condition of the cervix and the period of gestation. If it is definitely decided that some operative measure must be employed venesection may be omitted, as a sufficient amount of blood will be lost by the operation to bring about the desired drop in the blood pressure. Wherever the uterus can be emptied by simpler measures it should be done, and here venesection should be performed before delivery. Patients in the sixth or seventh months of pregnancy, either primiparæ or multiparæ and not in labor, may require a vaginal Cæsarean section in order to empty the uterus rapidly. In the

later months, when the child is viable, the patient, a multipara, cervix soft and dilatable, manual dilatation, with extraction by forceps or version, is the method that will give most success. Seldom will it be found necessary in these cases to perform abdominal Cæsarean section, unless other indications are present that necessitate this operation. The secret of success here will lie in the simplicity of the treatment instituted and the rapidity with which it can be executed. In primiparæ, however, at or near term, where convulsions are frequent or the patient in a state of coma, a different proposition confronts the physician. Examination will often reveal the cervix long, rigid, and practically undilatable. No good can come of delay here, and radical measures should be instituted at once. It is impossible to dilate such a cervix, and vaginal Cæsarean section is out of the question. Abdominal section is the only procedure left and should be performed without delay. I feel that this method of treatment in this class of cases admits of no argument against Cæsarean section, the only question being as to how quickly it should be done.

The entire question can be summed up in a few words—treat the patient before eclampsia develops and thereby eliminate eighty per cent. of the cases. When convulsions are unavoidable, treat in the simplest manner possible, allowing nature full scope, and when assistance becomes necessary use measures that will give results with a minimum amount of shock and trauma. Conservatism may be the method of choice, but radical measures have their place in the treatment of eclampsia. Each patient should be studied carefully and the method of treatment chosen should be the one best adapted for that individual case, and not chosen for the reason that it was successful in another case of eclampsia.

Radicular Pain and Its Relation to Spondylitis Deformans from a Neurological Viewpoint*

CHARLES ROSENHECK, M.D.
New York
Neurologist to the Hospital for Joint Diseases.

The subject of radicular or spinal root pain, whatever its origin, is one of infinite interest and importance. Obviously a great number of pathological states may be responsible for radicular disturbances, varying from inflammatory reactions to neoplastic processes. Radicular pain may be the expression of a purely local and limited process of a benign character or the reaction to a widespread and grave disease of the central nervous system. The spinal roots may be affected in their intradural or their extradural course. In either manner the effect is the same, viz., sharp, knifelike or lancinating, dull or boring, with or without paresthesia of various sorts, the description naturally varying in patients as do their emotional reactions to distressing situations.

It is not within the scope nor the purpose of this brief paper to give a detailed study of the affections that may be responsible for the radicular syndrome. The possibilities that call forth pain of a radicular type have been indicated in the introduction and need be dwelt upon no further. As the title indicates, the discussion will be limited to that form of radicular pain due to mechanical disturbances incidental to inflammatory disease of spinal vertebræ.

Orthopedists, whose attention is at all times focussed on the bony framework of the human body, have been quick to grasp the significance of this form of root pain. The profession in general, however, have missed the relationship between radicular disturbances and affections of the bony spine. In many instances personally observed the patient's complaint was not directed to the vertebræ. This was particularly true of spondylitis of a limited character. This in a measure may have directed the examiner's attention away from the seat of the disease. Obviously where the spondylitic process had involved the major part of the bony spine and the deformans stage reached the relationship between the radicular discomfort and the underlying bony affection was more readily established.

At the risk of repetition of a topic with which orthopedists are quite familiar an effort will be made, within the time limit imposed, to give in brief a neurological survey of cases of spondylitis that present themselves with symptoms of root irritation. At this point it may be of interest to note that one may see extensive disease of the bony vertebræ with practically no radicular involvement such as the *spondylose rhizomelique* of Marie. Then again the same amount of involvement may be responsible for an agonizing radiculitis similar to the types originally described by Bechterew. One may venture to explain this anomaly by the differences in the infectious agencies bringing about the spondylitis. Another point of interest may be here mentioned that even in the presence of most advanced forms of spondylitis deformans one never sees implication of the spinal cord parenchyma. One author notes that the cord readily adapts itself to various deforming attitudes of its bony encasement. We all can readily agree to this apparent fact. Neoplastic and tuberculous disease of the vertebræ obviously do not treat the cord with such benign consideration.

Excluding, therefore, the cord proper from direct involvement in the average case of spondylitis, we can readily explain the various phenomena that occur in this type of vertebral disease, as the result of irritation or compression of the spinal roots in their intervertebral course. In brief, these are paroxysmal or continuous pain, various paresthesias,

*Paper read before the Orthopedic Section of the New York Academy of Medicine, February 15, 1924.

either of a subjective or objective character, sensory and motor defects and reflex anomalies. The distribution and severity depend on the site, and extent of the implication. Not all of the above mentioned discomforts are necessarily present in every case. Complete and incomplete forms abound, such as are observed in any other disease picture. It may here be parenthetically stated that after observing a considerable number of cases of spondylitis with root symptoms, one is impressed by the amount of abuse the spinal roots can be subjected to without seriously crippling their functions.

In a study of the clinical forms of spondylitis with root symptoms, we purposely excluded the gross types of Bechterew or Strümpell-Marie from consideration. These are the true forms of spondylitis deformans, the manifestations of which are quite familiar to orthopedists. That form, however, wherein the spondylitic process was limited to several vertebræ, with concomitant radicular involvement interested us greatly. Most of these types (practically all one might say) showed involvement of the lumbar vertebræ or lumbosacral portion of the spine. While the x ray readily revealed the disease process in a majority of the cases, one was impressed by a considerable number that failed to show any pathology. We were quite sure, however, that in spite of the negative röntgen picture, the spondylitis existed. One may venture the supposition that in these cases, exudates about the nerve roots are responsible for the symptoms. Bony overgrowth is probably a later manifestation and hence more readily discernible on the plate.

The root symptoms were obviously in relation to the vertebræ involved, and were as a rule indefinitely localized by the patient. This can readily be explained by the fact that a number of roots are usually involved—some considerably, others very little. While sciatic pain distribution was common enough indicating involvement of the sacral roots, a number complained of pain sharply limited to the outer and anterior aspect of the thigh. In these cases it was evident that the upper lumbar roots had borne the brunt of the underlying bony pathology. In one case under observation the patient complained bitterly of a burning pain over a circumscribed area above the ankle.

It might be of interest at this point to mention that degenerative disease of the sciatic nerve—in other words a true neuritis—was not seen as often with spondylitis, as with sacroiliac affections. This marked difference may be explained by the fact that in spondylitis the roots are involved while sacroiliac disease affects the plexus, the latter being more vulnerable to neuritic changes. Plexus formation is relatively a later acquisition in the development of the peripheral neural apparatus, hence they are apt to succumb more readily to noxious influences.

The reflexes in a number of cases of spondylitis showed alterations worthy of mention. In the main the deep reflexes of the lower extremities were equal and exaggerated. A number, however, showed marked differences on both sides. A decided diminution to complete absence of one kneejerk was observed a number of times. Absence of both knee jerks with spondylitis would be an interesting phenomenon if observed. We have never seen it in the material at our disposal. The presence of unequal knee responses in persons past middle age need not necessarily imply lues of the spinal axis. Spondylitis of a localized character may be responsible for such reflex alterations.

And finally the treatment of radicular pain in these types of vertebral affections must engage our attention. Orthopedists are familiar with the therapeutic methods applicable to the underlying bony pathology and further comment on this phase seems unnecessary. Some do well with spinal immobilization. Others are less fortunate and continue to complain bitterly. We cannot share the optimism of those who state that effective immobilization stops the root pains. To these unfortunates we have advised intermittent confinement to bed for periods ranging from one to four weeks. Considerable and prolonged relief seemed to follow such treatment.

Laboratory Procedures of Interest to the Urologist*

LOUIS NERB
Brooklyn

There is perhaps no field in medicine in which the laboratory is more indispensable than in genitourinary work, and the multitude of ways in which the laboratory is of service as regards diagnosis and prognosis make it difficult to cover the field in one short paper.

While the field of laboratory work has broadened tremendously in the last few years we must not forget that our predecessors or we, ourselves, ten or more years ago, obtained much information from the means then at our command. A majority of the diseases affecting the kidney, ureter or bladder cause changes in the urine which are recognizable by the ordinary chemical and microscopical examination, and which together with the history and physical examination of the patient are sufficient to establish the diagnosis. On the other hand it must be admitted that these methods alone often fail to reveal the extent of the disease and that we occasionally see cases of advanced renal impairment which show no albumin or casts, and that we also see cases with no marked renal involvement which show both albumin and casts, and in which the condition is secondary to disturbances elsewhere in the body.

*From the Pathological Department of Brooklyn Hospital. Read before the Section of Genitourinary Surgery, New York Academy of Medicine, January 17, 1923.

With the advent of the functional tests, urology gained much in its accuracy of diagnosis and prognosis. The quantitative estimation of urea was formerly much relied upon, for giving a rough idea as to the functional ability of the kidney, but the great difficulty in drawing any conclusion from this knowledge was the fact that the quantity of the urea depended not only on the ability of the kidney to excrete this substance but also upon the amount of urea presented to it for excretion. With the perfection of the phenolsulphonephthalein test this difficulty was largely done away with, for a definitely known quantity of the dye can be administered to the patient and the amount excreted can be accurately measured. The test is a simple one, easy of administration and easy of interpretation. It is of value in almost all cases of renal impairment, particularly in the more advanced cases where the prognosis is uncertain and in surgical cases when it is considered essential to know the functional condition of the kidneys before operating. To perform this test it is necessary for it to be done with the utmost accuracy, inasmuch as we deal only with one c. c. of this dye, which we have to recover again in two hours in the urine. The average normal percentage for the excretion of phenolsulphonephthalein is fifty for the first hour and thirty to thirty-five for the second hour. If in two hours there is an excretion of less than forty per cent., the kidneys should be considered defective.

Mosenthal has devised a functional kidney test, which, though decidedly more elaborate, is satisfactory, as it practically points out to us with what kind of kidney lesion we have to deal. The test can be carried out in the patient's home, but is more likely to be accurate when done in the hospital. It consists of a study of specific gravity, nitrogen, salt and water excretion on specimens passed every two hours during the day and a twelve hour night urine, during twenty-four hours when the patient is on a standard renal diet. Normal urine shows considerable variation in the specific gravity readings, equal balance of salt, nitrogen and water, and a quantity of night urine usually under 400 c. c. Chronic interstitial nephritis shows a fixed low specific gravity, diminished salt and nitrogen excretion, polyuria and increased volume at night. Chronic parenchymatous nephritis shows a diminished salt and normal nitrogen excretion.

Then we come to one of the most important of our kidney tests—the examination of the cystoscopic urine specimen. This particular test enables us to ascertain with a certain accuracy which particular organ is impaired. As a rule the three separate specimens—bladder, right and left kidney urines are sent to the laboratory in sterile test tubes. The urines are separately cultured as a routine on glucose agar, the urea is determined and a careful microscopic examination of the sediment is made. In cases where numerous pus cells are found and the culture is sterile, a guineapig is injected in the abdominal cavity. The weight of the animal is determined and the animal is kept under observation for the next six weeks. If it loses weight and acts sick it is killed before six weeks and an autopsy performed. A guineapig positive for tuberculosis usually shows microscopical tubercles in the mesenteric glands, the liver and especially in the spleen. If there is any doubt, macroscopically, sections are cut and examined histologically. Strange to say, it sometimes happens that an inoculated guineapig gains in weight and shows no signs of sickness and yet at autopsy the spleen is seen to be studded with tubercles. Our diagnosis, therefore, cannot be based on observation of the animal alone, as a gain in weight does not exclude tuberculosis.

We have recently had several cases in the hospital in which some very interesting cultures were obtained by the use of the partial oxygen tension method. In one particular case of Dr. Rathbun's, a Streptococcus viridans was found in the root of an extracted tooth and also in the crypts of the freshly excised tonsils. Suspecting the same organism in the kidneys, as the patient was suffering from a pyelitis, the urine obtained by cystoscopy was cultured in the routine way on glucose agar and also by the low oxygen tension method. The latter tubes showed a luxuriant growth of Bacillus coli and a considerable number of small colonies of Streptococcus viridans. In this particular case it was easy to isolate the streptococcus, which was apparently the real cause of pyelitis, and to make a vaccine. Undoubtedly some of the streptococcus colonies might have been present in the glucose agar tube, cultured in the regular way, but those colonies were overgrown by the Bacillus coli, which multiply much more rapidly than the streptococcus in free oxygen.

Urine specimens showing a great many pus cells, with no organism, are directly examined for tubercle bacilli, before the guineapig is injected. Good results are sometimes obtained by allowing the urine to stand in the testtube overnight so that the sediment settles down gradually. The next day the supernatant fluid is carefully decanted and smears are taken from the upper layer of the sediment. The reason for taking the upper part is that the tubercle bacilli are lighter than the pus cells and other solids which are found in the urine, so the heavier particles sink to the bottom first and the lighter will stay on top. It has happened occasionally that a culture has been sterile, although Bacillus coli was seen in direct sediment examination, and such cases, on investigation, have shown that a small trace of a weak formaldehyde solution, present in the lumen of the catheter, was sufficient to inhibit the growth on the culture media. It is therefore very essential that the catheter is carefully freed of all antiseptics, inasmuch as a urine containing large numbers of pus cells is always suggestive of tuberculosis.

The estimation of urea from the separate kidneys gives us usually an indication of the relative functional ability, although I do not believe that a high urea analyzed by this particular method is an absolute indication of a better function. On the contrary it has occurred very frequently in the large number of examinations which we have done in the Brooklyn Hospital, that urine containing numerous pus cells and even organisms shows very frequently an urea output much higher than that of the normal kidney, and possibly within the normal limits of urea output, whereas the other kidney with negative microscopical findings and sterile culture, apparently a healthy kidney, shows an urea output much lower than that of the diseased kidney. Our records show

that of the last hundred cases of unilateral pyelitis fifty-one per cent. of the diseased kidneys had a higher urea output than the urea output of the healthy kidney. I think that the reason for this occurrence is this, that a patient lying on the table, forcing fluids, eliminates water very quickly through the normal kidney, such urine being clear, in appearance, with a specific gravity not much higher than water and usually with negative microscopical findings. The diseased kidney on the other hand practically does not eliminate the water at all. The amount is much less than from the other kidney. The urine is cloudy, contains a large number of solids and the urea is high, sometimes even higher than the normal urea output. It would appear to be old stagnant urine retained in the pelvis of the diseased kidney. Of course, if it were possible to leave the catheters in the individual kidneys for at least twelve hours at a time, collecting the specimens separately, it would probably be proved that the normal kidney, excreting water clear urine and less solids for a short time, would have at the end of twelve hours more urea in the total individual specimen than the other. This comparison, I believe, is only of value where one kidney is involved, and, as can be easily seen, the amount of urea, or in other words the higher output of urea in a specimen, collected in a short time, does not always indicate a healthier kidney, and the interpretation has to be done very cautiously, in connection with the microscopical findings and the culture. In cases like a bilateral pyelitis the amount of urea output in the separate kidneys is very often found to be approximately the same.

The phenolsulphonephthalein test seems the most valuable of our ordinary kidney function tests. If an injection is given to the patient while the catheters are in the individual ureters, we are able to ascertain the exact period of time before the dye begins to appear in the urine from each kidney. Ordinarily it is delayed if the kidney is diseased. When the patient is given an accurately measured amount of the dye, we also get practically the combined function of the kidneys. In the latter cases we may have difficulty in collecting the urine, especially in cases with obstruction, and if the urine contains free blood. Since we have been able to do simple blood analysis, it is possible for us to ascertain the functional ability of the kidney with much more accuracy, and practically independently of the analysis of the urine, but in measuring the activity of the individual kidney, the phenolsulphonephthalein test seems to be the most practicable.

The routine of blood analysis especially for the urological service consists of the determination of urea, creatinine, sugar and carbon dioxide. The latter especially if a high blood sugar is found.

The chief component of nonprotein nitrogen is urea and since the estimation of the latter is much simpler, we pay more attention to urea nitrogen or urea itself. Mosenthal and Hiller have made a careful study of the relation of the urea to the nonprotein nitrogen in disease. They point out that the selective action of the kidneys maintains the urea nitrogen at a level of fifty per cent. or less of the total nonprotein nitrogen of the blood, but that an impairment of renal function, even of very slight degree, may result in an increase of the percentage of urea nitrogen.

UREA

Urea is the end product of the aminoacids after they have undergone certain metabolic changes. The determination of urea has been much simplified on account of the discovery, by Marshall, of the action of urease (soya bean extract), in converting its nitrogen into ammonia which can be estimated by comparatively simple methods. To study the origin of urea a little more closely, it might be more easily understood by certain experiments which have been performed. If an animal is injected with aminoacids, the amount of aminonitrogen remains unchanged, except in the liver in which a rapid reduction is observed to occur. At the same time the percentage of urea in the blood steadily rises. The simplest interpretation of the result is, that the liver converts the aminoacid into urea and discharges this urea into the blood. But it must not be imagined that the conversion of the aminoacid into urea is exclusively a function of the liver. Certain experiments have shown that this process occurs even in animals from which the liver has been entirely removed. It is probably safe to conclude, however, that the liver is the most active centre for aminoacid transformation and urea formation. If samples of blood are estimated at short intervals of time after the ingestion of a large amount of protein, it is found that the increase becomes early established. Evidently the increase occurs about the same time as the passage of food from the stomach into the duodenum. The normal urea concentration in the blood is between twenty-four and thirty mgms. to the hundred c. c. of blood. The excess is supposed to be eliminated by the kidneys. There can be no doubt that the rate of nitrogen elimination as compared with the nitrogen intake, makes extremely important data from which important deductions with reference to kidney function can be made.

It is a great help to know what a nitrogen equilibrium is and to what an abnormal nitrogen retention can be attributed. The nitrogen equilibrium is defined as the ratio which is obtained by dividing the rate of intake of nitrogen by the rate of elimination. The equilibrium of nitrogen is well represented by a container, having an inverted syphon at the bottom, out of which water flows. If there is an inflow of water it will rise in this vessel until the pressure, due to the water level, is sufficient to produce an equal rate of outflow. In this way the water inflow is analogous to the intake of nitrogen, and the rate of outflow is similar to the rate of nitrogen excretion. The height to which the water must rise in order to cause the outflow to be equal to the inflow, is similar to the nitrogen content of the blood. Therefore if the rate of nitrogen elimination of the kidneys is reduced it is analogous to a small opening in the syphon, as the result of which the water will rise to a higher level or the nitrogen content in the blood will be comparatively higher, for the pressure of the nitrogen in the blood must be such that the excretion of nitrogen through the urine is equal to the intake of nitrogen in the food. The amount of nitrogen accumulated in the blood when the intake and the outflow are equal is therefore an indication of the function of the kidneys, in so far as nitrogen

metabolism is considered. The importance of the kidneys in removing the urea from the blood is readily seen from the changes in the percentage of urea in this fluid after the partial or complete removal of the kidneys. Animals survive nephrectomy for about three days, and during this time urea rapidly accumulates in the blood and begins to make its appearance in the saliva and the intestinal secretions. In men also, when the kidneys are extensively diseased, a similar accumulation of the urea occurs in the blood, some of the excess being got rid of through the sweat and to a certain extent through the intestines. The results obtained from chemical tests of the blood are therefore reliable and explain definite conditions which cannot as easily be diagnosed by other methods. After considerable experience in this class of cases it has been found that the patient showing urea nitrogen under twenty mgm. or urea under forty-five mgm. to the hundred c. c. of blood is a safe operative risk, whereas it is dangerous to operate when the urea is above sixty mgm. to the hundred c. c. of blood. The importance of low protein diet and encouraging perspiration and free movements of the bowels is thus especially indicated in borderline cases, especially where operation is not imminent.

CREATININE

There are approximately 120 grams of creatinine in the body of an average adult. A large proportion is in the muscle, the largest percentage is to be found in the voluntary muscles, the heart containing a medium percentage and the involuntary (intestinal) muscles containing comparatively a small percentage. The testes and the brain contain a trace more than the involuntary muscles. The liver, pancreas, thyroid, kidney and spleen contain traces. Human blood contains about one to two mgms. of creatinine per hundred c. c. of blood and this is almost equally distributed between plasma and the corpuscles. The creatinine content of the blood does not depend upon or vary with the supply of the food stuff and is therefore called the endproduct of endogenous metabolism. But although creatinine is an endogenous metabolite, part of it is derived from the food intake, but it is pretty well established that practically all the creatinine which is taken in by the food will be excreted through the kidneys by the urine. In normal individuals the amount of creatinine is from one to two mgms. per hundred c. c. of blood. But in the hospital we are forced to consider higher values of creatinine. Even in cases without renal involvement, we find very frequently creatinine figures between two and three mgm. that are not easily explained. Although in diabetes a slight retention of creatinine is usually found without any noticeable urea retention. In cases where we find a creatinine content of more than three mgm. almost always a high urea retention is encountered. It is frequently found that cases showing a creatinine content below four mgm. respond to treatment and improve gradually, but above four mgm. usually the reverse is true. Cases which show over five mgm. are invariably fatal within a short period of time. This rule does not hold good in acute cases, such as those due to arsenic or bichloride poisoning. In these latter cases the blood sometimes shows very high values of urea and creatinine though the patient ultimately might recover. By studying the creatinine more closely we may come to the conclusion that a retention of creatinine does not usually occur until the impairment of the kidneys is greatly advanced and the urea content in the blood is even higher than double the usual amount. It seems that the retention of creatinine is only of significance in cases which show a definite urea retention. That this should be is easily explained since creatinine is normally the easiest eliminated of all the nitrogenous waste products.

SUGAR

The most important part of blood sugar in urology is the indication of diabetic tendencies. As already mentioned previously, cases with nitrogen retention show usually a definite hyperglycemia in a moderate degree, which is generally not higher than 200 mgms. This type of hyperglycemia is not always combined with glycosuria. The normal sugar content in the blood is from 80 to 125 mgms. per 100 c. c. The threshold point, in which the kidney acting somewhat as a safety valve, begins to excrete sugar generally is about 170 to 180 mgms. There can, therefore, be a definite hyperglycemia without any glycosuria, or with merely a transient glycosuria, occurring one to two hours after a meal, when the amount of sugar in the blood temporarily exceeds the threshold point. This may occur in incipient or potential diabetic cases, in which the proper preventive treatment might check the progress of the disease. Cases of this type can be easily operated upon without danger after they respond to treatment.

CARBON DIOXIDE

In cases showing any evidence of nitrogen retention or hyperglycemia, the carbon dioxide combining power is ascertained because of the danger of acidosis. The essential cause of acidosis may either come from the addition of foreign acids added to the blood as found in diabetis, or as in nephritis through the acids of a normal metabolism accumulated because of faulty excretion through the kidneys. Healthy blood maintains a constant slight alkalinity, through the influence of the bicarbonates, phosphates and proteins in the blood. The most common methods of measuring the degree of acidosis suggested in most textbooks are: 1, lowered carbon dioxide combining power of the blood; 2, lowered alveolar air tension; 3, decreased affinity of hemoglobin for oxygen; 4, increased hydrogen ion concentration of the blood and retention of alkali by the body in cases where the kidney is able to rapidly excrete an excess of alkali. The test most frequently used in most laboratories and from which the best results have been obtained is the carbon dioxide combining power of the blood, determined by the Van Slyke method. By administration of certain amounts of sodium bicarbonate the depletion of this chemical can be readily determined and has been in practical use for several years. The reaction of urine in normal persons can be easily changed by administration of ten grams sodium bicarbonate, whereas in acidosis of advanced nephritis the deficiency may amount to even more than 100 grams of this chemical.

Palmer and Van Slyke have carefully studied this question in connection with carbon dioxide combining power in the blood. They found that in most pathological cases the urine did not become

more alkaline than the blood until a higher plasma bicarbonate had been reached than in normal individuals. If the administration of bicarbonate should be continued, which was the usual clinical procedure, it would result in giving the patient an injurious amount of alkali. Palmer and Van Slyke point out the importance of carefully controlling the therapeutic use of sodium bicarbonate. They have calculated that taking forty-two pounds as the unit 0.5 grams of sodium bicarbonate will raise the plasma carbon dioxide ten per cent. per volume. Taking this as a standard it is easy to calculate the amount of alkali necessary to restore the plasma bicarbonate to normal. The normal range of carbon dioxide combining power of the blood is from fifty-five to seventy-seven c. c. to the hundred c. c. of plasma. In fatal cases with a marked nitrogen retention a severe acidosis is usually found, which is sufficient to be the actual cause of death. Therefore we may easily come to the conclusion that cases of carbon dioxide volume below forty-five c. c. show a beginning acidosis and are a bad operative risk. In these cases it may be worth while to try the sodium bicarbonate treatment, eventually intravenously with which some excellent results have been obtained.

SUMMARY AND CONCLUSION

After having taken up all these individual tests we may easily come to the conclusion that the preoperative information of the blood chemistry is necessary in all surgical cases, but especially in all surgical conditions of the kidney, ureter, bladder and prostate.

We have found that the estimation of urea is the most helpful of all our tests for the urological service, although if urea is above the normal limits (forty-five mgm. to the 100 c. c. of blood) the determination of carbon dioxide creatinin and sugar is essential.

Local Anesthesia for Dental, Oral, Nose and Throat Surgeons

Fourth Article*

H. E. TOMPKINS, M.D., D.D.S.
New York.

THE ANTERIOR ETHMOIDAL FORAMEN

Synonyms.—Anterior ethmoidal foramen; Peukert's; median orbital, etc.

Object.—To reach the anterior ethmoidal foramen and there anesthetize the branch of the nasociliary that passes through it.

Location.—The anterior ethmoidal foramen is located on the internal orbital wall just above the ethmoidal cells, on a horizontal plane with the topmost point of the nasofrontal suture, at a depth of approximately fifteen to twenty-five mm. inward.

Prepare solution.—Prepare four mils of one per cent. procaine solution to which should be added one drop of suprarenal extract which gives an equivalent of about one to 60,000. This quantity of solution includes an excess of two and a half mils.

Select needle.—Select a sterile needle forty-two mm. in length, of 23 gauge, equipped with a hub to fit the syringe. (Many operators make an initial injection into the area into which the needle mentioned above is to enter for the purpose of making the entrance of the needle painless. For this they use a needle twenty-five mm. long and of 25 to 27 gauge. It is my opinion that the entrance of the smaller needle is quite as painful as that of the larger, therefore I do not recommend the use of the smaller needle nor the preliminary injection into the area.)

Syringe.—The syringe best adapted to this injection is either a two c. c. Luer or a two c. c. Record.

Fill syringe with solution, invert so its point is upward, expel air bubbles, attach needle and again expel air bubbles. Wash the skin about the inner canthus of the eye well and thoroughly with soap and water. Wipe with alcohol and dry. Paint the area with the iodine mixture. Be careful that none of the water, the alcohol nor the iodine mixture is allowed to get into the eye. Be careful to follow the technic of the test injection as given under Note No. 7.

Preliminary medication.—Bromural, ten grains; or morphine, one quarter grain, either alone or in combination, should be administered as a preliminary to render the patient complacent.

The patient should be either semirecumbent or fully reclining during and for five to ten minutes after the injection. About five minutes before the actual injection, place a few drops of ten per cent. procaine solution, with suprarenal extract, in the proportion of one to 60,000, in the eye under the lid.

Specific technic.—Enter the needle into the skin about three mm. above the extreme inner angle of the inner canthus of the eye. This point is internal to the conjunctiva and is on a horizontal line with the highest point of the suture of the nasal and frontal bones. The syringe and needle is held in line with a horizontal plane of the head (when erect) and should point in a sagital direction or directly straight from front to back. The needle should enter the skin and immediately glance over the periosteum of the bony prominence (the internal angular process of the frontal bone). The bevel of the needle should be toward bone. Advance the needle along the periosteum in the direction given, being careful to keep the side of the point of the needle in contact with bone or periosteum.

At a depth of approximately twenty mm., a sort of empty space is felt at the needle point. This is the depression formed by the anterior ethmoidal foramen and here lies the anterior ethmoidal (nasal) branch of the nasociliary nerve as well as its accompanying artery and vein. At this point inject one and a half mils of the prepared solution, slowly. Take

*The first article in the series was published in our issue for October 19, 1921; the second in February 1, 1922, and the third in March 1, 1922.

two to three minutes to inject the quantity mentioned. Do not inject the solution until the depression is felt with the needle, except that if pain is evinced during the advance of the needle, a small amount of solution may be sent just in advance of the needle. The foramen may vary as to depth depending upon the size of the head; fifteen to twenty-five mm. are the extremes found in my experience. Its presence is indicated by the feeling of the socalled empty space.

Withdraw the needle, see that it is in its proper place on its hub. Wait from five to twenty minutes for anesthesia which will be indicated by absence of pain upon pricking the membrane of the tip of the nose, on the side injected. Of course, anesthesia is present only on the side of the injection.

Nerve complications.—It is to be remembered that the nasal branch of the nasociliary carries sensation to that portion of the nose, its septum, lateral walls and communicating sinuses and cells, that lies anterior to a line drawn from the incisive canal (anterior palatine foramen) below to the centre of the cribiform plate. Posterior to this line, the nasal cavity is innervated by branches from the sphenopalatine ganglion, except in the area of the posterior ethmoidal cells and the sphenoidal sinus which is innervated by the posterior ethmoidal branch of the nasociliary and by the olfactory. That area supplied by the posterior ethmoidal is best anesthetized by a twenty per cent. procaine pack or spray. The maxillary sinus and its walls are innervated by branches of the infraorbital and from the sphenopalatine ganglion. The skin of the nose, overlying the nasal bone and superior to the cartilages, is supplied by the nasal branches of the infraorbital.

Accidents.—The needle may break. The needle may be deflected from its proper course, injury to the conjunctiva or orbit may result. Terminal branches of the ophthalmic artery may be punctured or minor veins in the part may be punctured with the result that hematoma will follow. (Such puncture hematoma are unpleasant but not at all dangerous. They simply cause a bulging of the eye and the surrounding tissue for a short time, this is followed by a suffusion of the lids (black eye) which passes away in a few days.) But such accidents are not likely to happen if the technic is followed carefully. As a further guide and precaution during the insertion of the needle, the bulb or orbit may be displaced or pushed to one side away from the site of puncture. The finger which holds the orbit out of the way serves as a guide for the needle from the outside. The needle must be in contact with bone or periosteum throughout the journey to the foramen and must not be permitted to bend.

Remarks.—The anesthesia resulting from this injection covers that portion of the nose anterior to a line drawn from the incisive canal to the centre of the cribiform plate and includes the membrane covering or lining the anterior ethmoidal cells and the frontal sinus.

POSTERIOR ETHMOIDAL CELLS, SPHENOIDAL SINUS

Continue to advance the needle in the direction given above, picking up bone once more. Advance the needle to a point within about five mm. of the posterior ethmoidal foramen which means that the needle should be advanced to a depth not to exceed a total of thirty mm. or ten mm. further or deeper than for the anterior ethmoidal foramen. To advance the needle to a greater depth is to invite trouble such as surrounding the optic nerve with solution or to puncture that nerve. It is better practice to pack, spray or paint that area with twenty per cent. procaine solution or the socalled mud.

KILLIAN'S PUNCTURES

This name is frequently given to infiltration injections made at some point or points along the course of the nasal, nasopalatine or the lateral nasal branches of the sphenopalatine ganglion. Injections are made at two points: 1, just anterior to the tuberculum septi in an upward direction, and 2, at a point just below the middle of the lower border of the middle turbinate. The pain induced by the introduction of the needle into and under the membrane is so decidedly unpleasant that most surgeons resort to the pack or spray.

THE INJECTION AT MECKEL'S GANGLION

Synonyms.—Meckel's ganglion; sphenopalatine.

Object.—To reach the ganglion and anesthetize its branches.

Location.—Meckel's ganglion is situated in the sphenopalatine fossa about six to ten mm, below the sphenomaxillary (inferior orbital) fissure.

Prepare solution.—Prepare four mils of one per cent. procaine solution to which add one drop of suprarenal extract; this results in a proportion of about one to 60,000. The quantity mentioned contains an excess of one and a half to two mils.

Select needle.—The needle used for this injection is the same as that described and used for the injection into the posterior infraorbital area. The syringe best adapted to this injection is either a three c. c. Luer or a three c. c. Record.

Meckel's ganglion may be reached and anesthetized by any one of four routes.

1. By diffusion from the injection into the posterior infraorbital area. This injection has already been described.

2. By a direct route somewhat similar to the above. This is known as the external route.

3. By a route above and behind the tuberosity, called the posttuberosity route.

4. By way of the posterior palatine canal, known as the canal route. This route is probably the easiest, simplest and most efficient of the four.

To reach Meckel's ganglion by the external route, make the test injection described under Note No. 7. To prepare, cleanse the area in the mucous fold above the last two molar teeth. Paint with the iodine mixture.

Specific technic.—With the index finger hold the cheek away from the molar teeth so the view will be unobstructed. It is well to have the patient's mouth partly closed so there will be no strain on any muscles. Enter the needle point into the highest part of the mucous fold above the middle of the third molar tooth (the last molar present or about to erupt in younger subjects) but about twelve mm. external to the gum. Because of the peculiar shape and length of the needle, its entrance must be made nearly parallel with the plane of occlusion, yet the angle at which it is entered should be as great as the partly closed mouth will permit.

After the needle point has entered the tissue, it should be pointed upward and inward toward the median line, endeavoring to carry it upward and inward at an angle of about 45° when viewed from the front but, if it could be seen from the side, the needle proper would be nearly vertical. Advance the needle upward in the direction given. After about fifteen mm. of its length has entered the tissue, the side of its point should touch bone. Continue to advance the needle in the direction given, keeping the side of its point in contact with bone, until about twenty-five mm. of its length shall have entered the tissue. During the advance of the needle do not allow the needle point to engage the periosteum since, in that case, it will be impossible to properly direct the needle. The needle point should now be in the sphenopalatine fossa and not more than five mm. away from the ganglion. Here inject from two to two and a half mils of one per cent. procaine solution. Do this slowly. Take three minutes to inject the quantity mentioned.

Withdraw the needle from the tissue, see that it is in its proper place on the hub. Wait from five to twenty minutes for anesthesia to appear.

To reach Meckel's ganglion by the posttuberosity route: Cleanse the mucous membrane around the tuberosity. Paint with the iodine mixture.

Specific technic.—With the mouth wide open, the needle is entered into the tissue at the posteroexternal angle of the tuberosity, in such a position that the pterygoid process shall be missed. The needle is carried directly upward, keeping its point in contact with the posterior surface of the maxilla, until twenty-five mm. of its length shall have been entered into the tissue. The needle point should now be in the sphenopalatine fossa and less than five mm. from the ganglion. Here inject from two to two and a half mils of one per cent. procaine solution. Do this slowly. Take three minutes to inject the quantity mentioned. Withdraw the needle from the tissue and see that it is in its proper place on the hub.

During the advance of the needle, great care must be exercised to keep its point in contact with the posterior surface of the maxilla and to go straight upward. A slight deflection toward the median line will cause the point of the needle to engage or strike the pterygoid process of the sphenoid bone. No damage can result from this deflection except that it will be impossible to reach the desired location and, further, the external pterygoid muscle may be pierced and infiltrated at its attachment thus producing a transcient trismus. If the pterygoid process is struck, withdraw the needle and start again a little more external to the original point.

Great care must be exercised, also, in the passage of the needle to its proper location that the needle shall not be bent nor broken. The extension of the shank of the needle and the length of the syringe makes a very long lever. The tendency is to advance the needle by using the syringe as the lever. This invariably causes the needle to bend. It is better to place the finger under the angle of the needle and to advance the needle by the direct pressure thus applied, while the other hand steadies the syringe.

To reach Meckel's ganglion by the canal route: Cleanse the mucous membrane around the posterior palatine foramen. Paint with the iodine mixture. Remember the location of the posterior palatine canal. Its palatine opening is situated above the last molar tooth erupted but at the junction of the alveolar process and the hard palate.

Specific technic.—Have the patient open his mouth as wide as possible. With the needle as nearly vertical as the opened jaws will permit, enter its point into the mucous membrane under the opening of the canal but close to the alveolar border of the foramen. The needle is entered to the side to avoid puncturing the artery or vein passing through the foramen. In the majority of cases access to the foramen is easy because of its funnelshaped opening.

Having entered the needle into the foramen, advance it slowly and carefully up through the canal being guided in direction by the walls of the canal. Great care must be exercised during the advance of the needle, for frequently the canal is tortuous, so much so in a certain few cases that it is impossible to carry the needle the full length of the canal. Happily, however, about ninety per cent. of the cases have comparatively large and fairly straight canals, quite easy of access.

Having passed through the canal with the needle, its advance should be stopped at a depth of about twenty to thirty mm. (average depth twenty-five mm.) depending upon the age of the patient and the development of the parts. At this point the needle is seldom more than from three to five mm. from the ganglion. Here one and a half mils of one per cent. procaine solution (with suprarenal extract in the proportion of one to 50,000) is injected slowly, taking no less than two minutes to inject. Up to this point one half mil of solution has been injected, throughout the canal and just in advance of the needle, to make its progress painless. Anesthesia will present throughout the distribution of the branches of Meckel's ganglion in from five to twenty minutes and will persist for an average period of about one hour.

By carrying the needle about five mm. deeper, its point will be brought into close proximity to the trunk of the superior maxillary division as it passes across the sphenopalatine and the sphenomaxillary fossæ. The injection of about half a mil of solution during the passage of the needle through the canal, the injection of about one mil of solution at or near the ganglion and the injection of one mil of solution at or near the superior maxillary division will result in an anesthesia of the entire distribution of the superior maxillary division of the trifacial nerve (of course, distal to the site of the injection) except that area in which the anastomosis of the branches of the two trunks occur.

Accidents.—The needle may break. The construction of the needle and shank used for the four routes mentioned next above, renders breakage of the needle extremely easy. Fortunately the weakest point is at the junction of the needle and the shank. Since the needle proper is one and five eighths inches in length about one half inch of needle is left exposed to view. This may be grasped with forceps and removed in the event of breakage.

Hematoma may follow careless insertion of the needle, due to puncture of a vein or artery. The use of a 45° angle point on the needle helps to prevent punctures to a great extent.

Soreness, fainting, shock or collapse will follow the use of old, discolored, unclean or nonisotonic solutions or solutions containing too great a percentage of suprarenal extract. This applies to all injections.

Infection and dangerous abscesses will follow the use of unclean instruments. This applies to all work.

None of these accidents will happen, however, if the technic has been followed.

Area of anesthesia.—Injection at Meckel's ganglion results in anesthesia of the entire nasal cavity (except that portion above and anterior to the anterior border of the vomer bone), of the entire nasopharynx, of the oropharynx as far down as about the middle of the middle constrictor muscle including the floor of the nose, the hard and soft palates, the pillars of the fauces and the upper portion of the tonsils and of the maxillary sinus except a part of the external wall. In other words, anesthesia is present in all of the area to which branches of the ganglion distribute.

INJECTION AT THE ACCESSORY POSTERIOR PALATINE FORAMINA

Object.—To reach and anesthetize the middle and posterior palatine nerves as they emerge from their conducting foramina.

Location.—The accessory posterior palatine foramina are situated, one just back of the posterior palatine foramen but in front of the hamular process and the other just posterior to the posterior border of the tuberosity as formed by the alveolar process.

Prepare three mils of one and a half per cent. procaine solution, this quantity includes an excess of one and a half mils. To the solution thus prepared add one drop of suprarenal extract thus producing an equivalent of about one to 45,000. Select a sterile needle, twenty-five mm. in length and of twenty-three gauge equipped with a hub to fit the syringe. The syringe best adapted to this injection is either a two c. c. Luer or a two c. c. Record. Fill the syringe with solution, invert so its point is upward, expel air bubbles, attach needle and again expel air bubbles. Paint the area with the iodine mixture.

Specific technic.—Directing the syringe and needle from the opposite side of the mouth, enter the needle point into the mucous membrane at a point just under the posterior border of the posterior palatine foramen. Advance the needle to a depth of about three mm. and inject a few drops of solution, continue to advance the needle, still directing it from the opposite side of the mouth, until its point shall be just beyond the middle of the posterior border of the alveolar process but deep in the groove formed by the junction of the wing of the sphenoid and the superior maxillary bone. As a rule there is an overhanging shelf of alveolar process over the groove, whose sidewall is fairly smooth. Try to follow the wall of this shelf of process.

At this point inject about three quarter mil of procaine solution, withdraw the needle slightly and inject more solution, again withdraw the needle a little and inject still more. Continue this until the needle shall be withdrawn from the tissue and a total of one and a half mils of solution shall have been injected.

Anesthesia of the soft palate and the pillars will result in from five to ten minutes. The anesthesia resulting from this injection is not quite as thoroughly satisfactory as could be wished particularly for tonsillectomy though for operations on the uvula and the soft palate it is very pleasing. The injection of choice for work in the pharynx and on the palate is that of Meckel's ganglion by the canal route.

(*To be concluded*)

Some Anomalies in Laryngology

SAMUEL COHEN, M.D.

Philadelphia, Pa.

An anomaly is a condition unusual enough to attract attention, and some anomalies may assume a rather important place in the study of disease. Especially so when their misplaced position or function so acts upon the rest of the body as to bring untoward results. Other anomalies are of no more importance than that of scientific interest and curiosity, having no actual bearing upon the economy.

THREE ANOMALIES

I wish to cite three anomalies. 1. The styloid process, protruding into the sinus tonsillaris and producing no harm whatsoever; only being accidently recognized after the tonsils had been removed. 2. The carotid artery pulsating behind the tonsils. This was rather important, in that it showed the possible danger in operating in a situation of this kind, and proves the necessity of a thorough study of the tonsillar anatomy including that of the surrounding structures before advising their removal. 3. A supernumerary tongue; this is of unusual rarity, and I believe the first case on record. It had to be removed because it was interfering with the respiratory function.

The styloid process is part of the hyoid bar (from the second branchial cleft) which joins the temporal bone under cover of the vaginal process. It is thick at its origin but presently becomes thinner ending in a sharp point. It is usually about one inch long but varies greatly. It runs downward, forward, and inward, and is continued as the stylohyoid ligament to the lesser cornu of the hyoid bone (Piersol).

In lower animals it appears that the size and shape of the styloid process depends upon the amount of tongue motion present in that particular animal. The styloid process of the horse is comparatively short and slender, and the tongue motility is correspondingly small. In other animals like the ox or dog, the styloid process assumes rather large proportions. In some animals it does not end in a point, but is flat and often doubled at its free margin, forming a strong base for muscular attachments. In these animals the tongue motion is found to be great. (These

suggestions have been made to me by Dr. Lentz of the veterinary department of the University of Pennsylvania.)

The following is a case presented before the Philadelphia Laryngological Society:

Case I.—Mr. T. G., aged twenty-nine, came to me with a history of several attacks of pain in the joints following an attack of tonsillitis over a year ago. The family history was negative. The previous medical history, scarlet fever at the age of five, several attacks of follicular tonsillitis. Under apothesine (one half of one per cent.) local anesthesia, by the dissection and snare method both tonsils were removed. On inspecting the tonsillar fossæ, a protrusion was noted on the lower lateral walls. On palpation, these were found to be pointed hard and about half an inch in length. The diagnosis of styloid process protruding into the sinus tonsillaris was made. The patient made an uneventful recovery.

There are cases on record (and probably many that have not been recorded) where the carotid or some other large vessel has been injured during the socalled simple tonsil operation with fatal terminations. Before citing the next case I can do no better than repeat verbatim the conclusions of Dr. J. Parsons Schaeffer (1).

1. It would appear that, in addition to a painstaking inspection, careful palpation of the tonsillar field should be practised in all cases preliminary to a tonsillectomy, in order to judge the nearness of large or aberrant bloodvessels. The red flag of danger appears when the superior constrictor muscle and the thin buccopharyngeal fascia are inadvertently torn in operative procedures.

2. The large artery frequently visible in the wall of the oral pharynx and in intimate topographical relationship with the palatine or faucial tonsil is usually a redundant and tortuous internal carotid. The common carotid stem in the absence of the internal carotid, the external carotid, and the ascending pharyngeal and the ascending palatine arteries, likewise, at times, give rise to visible pharyngeal pulsation.

3. The redundant or tortuous internal carotid artery and agenesis of the internal carotid proper, represent a reversion to more primitive types.

4. Age has no bearing on the development and presence of a tortuous internal carotid artery.

Case II.—F. K., aged seven, came to the Howard Hospital dispensary, with a note from the school doctor, asking for a tonsillectomy. The family history was negative. Previous medical history, measles and one attack of tonsillitis. The heart and lungs were normal. Examination showed the anterior cervical to be glands palpable. The teeth were clinically negative. The tonsils did not protrude in front of the anterior pillars. There was no pus on pressure. The anterior pillars were not adherent to the tonsils. Many crypts were seen. Behind each posterior pillar and running parallel to them a pulsating vessel was noted. The size of the pulsating vessel was about that of an ordinary lead pencil. It could be traced to a little above the soft palate, then seemed to disappear outward and forward. After consultations with Dr. Wood, Dr. Hunter, and the rest of our staff, we decided to refer this child for x ray treatments, believing the operative risks too big. Several x ray treatments produced in my opinion no appreciable diminution in size of the tonsils, some of the staff, however, thought there might be a slight reduction in size.

This case of the supernumerary tongue is of interest because of its extreme rarity. I have been unable to find another case like it in the literature. Specimen presented before the Section on Otology and Laryngology, College of Physicians and Surgeons of Philadelphia. By courtesy of Dr. Wood.

Case III.—The patient, S. C., aged ten days, was brought to my office by Dr. A. with the following history: Dr. A. delivered the child and soon after birth noticed a difficulty in breathing, especially on inspiration. A peculiar noise or gurgling sound was heard continually. The child was almost continually cyanotic. The breathing became easier on holding the head low down. After several attempts Dr. A. was able to notice a foreign body in the throat and then brought the child to my office.

Examination showed the following: Weight seven pounds, mouth open, breathing noisy, floppy and gurgling, retraction on the supersternal notch and spaces between the ribs. Examination of the throat showed a peculiar body lying in the pharynx, more toward the left, parallel to the long axis of the pharynx. Breathing caused it to move either up or down or to slip over the tongue, bringing itself into plain view. When lying on the tongue this body appeared the duplicate of the tongue, so much that Dr. A. and myself both agreed that it was a case of double tongue. The child breathed almost normally as soon as this mass was grasped and held forward. On inserting my finger I found that the mass sprang from the left pharyngeal wall behind the left posterior tonsillar pillar on a level with the soft palate. By means of a snare this mass was removed as near as possible to its base. It was then sent to the pathologist of the Howard Hospital, Dr. John D. Paul, for examination and report, being careful not to tell the pathologist that we thought it was another tongue. His report is attached hereto. The child is almost a year old now and is in perfect health.

The specimen is a moderately firm, elongated, pinkish gray mass measuring 3.5 by 1.2 by one cm. The tip and edges are rounded. The posterior end is contracted like a pedicle. The posterior surface is slightly rough and in its posterior third the midline is marked by a shallow groove. The anterior or inferior surface is more smooth than the upper and marked in the midline by a slightly elevated ridge.

Microscopically this mass consists of principally vertical, transverse, and longitudinal striped muscle fibres running approximately at right angles to each other. This muscle tissue is surrounded by squamous epithelium resting on a tunica propria which is in turn supported by a submucosa of loose connective tissue. On the upper of posterior surface of the mass there are numerous mushroom like elevations of the connective tissue covered with a thin layer of squamous epithelium (fungiform papillæ). In the deeper portions of the tunica propria and in a few instances down between the muscle bundles are a few tuboalveolar glands lined with low cuboidal epithelium resting on a delicate basement membrane.

The specimen has the gross and microscopic appearance of a tongue.

2009 Pine Street.

Practical Therapeutics

A SUGGESTED MEANS OF ADMINISTERING CHLORINE GAS WITHOUT SPECIAL APPARATUS*

FREDERICK S. MACY, M.D.

Brooklyn, New York

Late Lieutenant Colonel, Medical Corps, U. S. Army,
Major, U. S. Army, Retired.

The purpose of this brief note is not to discuss the merits of chlorine gas in the treatment of diseases of the respiratory tract, but simply to suggest a convenient, safe method whereby the patient may be given the gas at home or elsewhere when his physician considers it an appropriate remedy. I devised the method while searching for an expedient to use in a welfare case, which I will summarize briefly.

CASE.—The man, H. H., a clerk, in late middle life, had neglected a cough and hoarseness which had persisted during an indefinite period and was more noticeable to others than to himself. He was tall and thin, of cheerful disposition, inclined to be vacillating, and tended toward the blond rather than the brunette type. In August, 1923, a diagnosis of chronic, advanced pulmonary tuberculosis of both lungs was made by a local Board of Health clinic and was confirmed microscopically. Conditions were particularly unfavorable hygienically, since he was too weak to work and therefore was compelled to live in an unhealthful city street in a cheap tenement over a damp, earth cellar. A family of young children added to his distress mentally and his wife was unable to secure employment sufficiently lucrative to support a home. He was thus an object of charity and largely dependent upon the gratuities of associations and neighbors.

The local Board of Health sent him to a sanatorium, but he was put to work there, he asserted, and was physically unable to endure the labor. At any rate he returned to his squalid home in much worse condition than when he left it, and soon afterward experienced two hemorrhages in quick succession. Shortly after this episode he set out to visit the public clinic again, but collapsed on the street *en route* and was taken to a hospital by ambulance. He again returned home, and lapsed into a state of profound prostration which the visiting physicians, sent him by a benefit association, considered terminal. In talking with some of these gentlemen afterward about the case they all stated that they considered it hopeless and that he was practically moribund. At this crisis a brother in the West offered to provide funds for his removal and maintenance in the country, but it was doubted whether he could safely be moved even to a railroad train.

This human and unfortunately too common tragedy, brought casually to my attention by a friend, led me to suggest that perhaps chlorine gas would hold the disease in sufficient abeyance and permit him to recuperate to a degree that would enable him to take advantage of his brother's offer long enough, at least, so that he might die in decent surroundings. Then arose the question of administration. I decided to try evolving the gas from solution by spreading this over a considerable, freely exposed surface. To this end I obtained from a dispensary a supply of a solution of the Carrel-Dakin order, as a possible source of free chlorine. A medium sized Turkish towel thoroughly soaked with this presented a surface area for dissipating the gas and was suspended a few inches above the patient's head. A knot in the lower end guarded against possible drip. The patient lay quietly at ease in bed, the window open sufficiently to insure normal ventilation.

The odor of the gas was plainly perceptible on the floor of the tenement house below, yet he experienced no discomfort, inconvenience or irritation whatsoever. It would obviously have been a simple matter to adjust if he had. The exposure was continued throughout the entire twenty-four hours on each of the succeeding days, and after the third day a distinct change occurred in the sputum. Instead of the ugly, bloody spectacle presented in such cases the expectoration gradually increased in quantity, though the attacks of coughing did not, either in number or severity, and became glairy, transparent and more homogeneous. The blood gradually disappeared. Little by little the cough decreased and sleep improved, so that at the end of about three weeks he habitually slept all night. Upon waking there would be a period of coughing characterized by free expectoration without exhausting, racking effort, and after that he would be troubled very little with cough throughout the day.

By degrees another change supervened in the sputum, manifested by a brown discoloration, possibly due to the granular débris of dead material undergoing disintegration or solution. At the end of about a month he was up and about rather more than was good for him and contrary to advice, so that he improvised, himself, certain modifications of the towel method. For example, he made a paper cone, lined it like an old fashioned ether mask, and sat at his window inhaling from it. This, I felt, was a possibly risky method, especially since, to use his own words, he "just poured on the solution and dug his nose into it." However, he was none the worse for his experiment, and at the end of six weeks, using the gas *ad lib.*, all pain, soreness and discomfort had disappeared, so that he could take his breath "all the way down," as he put it.

At about this time he decided to visit the Board of Health clinic and made the trip, a considerable ride on street cars, without effort, he said, denying any weariness. Needless to say he had been provided with good reconstructives during his treatment. Immediately afterward he crossed the city to tell me of the event, very happy indeed. He said that they had seemed greatly surprised when he came in, and much more so at his greatly improved state. The doctor who examined him, rather perfunctorily at first, he declared, "listened, cocked his head, and then got down to business." Then, it seems, they all examined him and plied him with many questions as to what he had been taking, how he took it, where he obtained it, and advised him by all means to con-

*Published by permission of the Surgeon General.

tinue. The verdict was, he said, that the left lung had "cleared up" and that the right was very bad indeed but very much better. About a week later he went to a resort in the lower Adirondacks and wrote that he was "feeling fine."

I venture no predictions concerning this case. The most I can say is that he survived a crisis that apparently was terminal, and that since the only change in food, hygiene or treatment consisted in the addition of the extemporized method of giving him chlorine as described, we are justified in crediting that method with efficacy in this particular instance. Since this patient was unquestionably benefited, others to whom I have suggested using the gas in the same way, as well as I myself, have tried it in other cases ranging in severity from simple coryza to graver and more chronic infections of the respiratory system, with encouraging results, so that I feel justified in suggesting the method for further trial as a useful expedient.

It presents, also, certain advantages which are, briefly, the total elimination of danger from storage or supply tanks; no special apparatus is required; it is available practically everywhere, in bed at home, for example, at any and all times; the gas can be administered, if desired, continuously throughout the twenty-four hours, which is well worth considering when one reflects that the number of bacteria destroyed or inhibited during the conventional short exposure is nothing in comparison with the number that may be reproduced during the balance of the twenty-four hours; sufficient air interchange is not interfered with since the gas gravitates downward and thus tends to minimize loss; the method is practically fool proof; and what is in some respects most important, seems to permit a lower dilution for a longer period without irritation than is possible with the chamber method. And there is still one more point worth considering, for not only does the patient receive the gas, but so also do contacts, prophylactically. It seems to exemplify the tried and true doctrine that best results are obtained by small doses oft repeated.

Naturally, the relative percentage of gas obtainable by this extemporization will depend largely upon the size of the room and the chlorine solution selected. In the particular case I have cited the room was a small one. As for the solution, we have tried different kinds with varying degrees of success, but those which have been prepared electrolytically seem most efficient. This may be because in such solutions the gas is nascent rather than molecular, probably, or because there is bound to be present a certain amount of free oxygen also. At any rate, there is no question that more available free gas is obtained.

Admittedly the method suggested is lacking in technically scientific merit. But that is no reason for denying the benefit of it to suitable cases in which the patients otherwise would not get the gas at all. One would hardly let a man bleed to death in the street because of the lack of a scientifically constructed tourniquet with accurate pressure gauge refinements. He very certainly would adopt any convenient expedient, and I am simply offering this, also, as a possible aid and even a lifesaving improvisation.

DEFICIENCY OF THE HALOGENS IN MODERN DIETETICS*

C. Edgerton Carter, M.D.

Los Angeles, Cal.

(*Concluded from page 176*)

Susceptibility to disease, at least in rats, depends upon constitutional factors, not the least of which is the thyroid's ability to function effectively. Child presents evidence that "susceptibility and recovery vary in general directly with, though not necessarily proportionally to, the rate of oxidative metabolism" (16).

It is hardly necessary to carry these suggestions further. There is ample material for an analysis of underlying conditions in simple goitre, cretinoid types, nervous and neurotic manifestations, rachitis and beginning epilepsy, all suggesting that there are dietetic deficiencies. Correction of these may result, possibly, even in a modicum of cancerous prevention. Suboxidation, with the consequent disturbance of normal cell activity through imbalance of required minerals and salts, appears to be present in all of the conditions outlined above. It is generally agreed, furthermore, that the predisposing factors of infection and the physiological conditions causing hyperactivity of the thyroid may all contribute to a depletion of the stored thyroxin. The keynote is sounded in one short statement of Klein's (17), viz., "if the demand is too great, pathological changes ensue," and Marine maintains that active hyperplasia or disease of the thyroid occurs if the iodine content falls below 0.1 of one per cent.

Consequently, it would seem to be the path of prudence to adopt some method by which a sufficient halogen intake could be assured the thyroid, at least in the stress of emergency. This has been rather startlingly corroborated at the Mayo Clinic, by the practice adopted within the last few months of iodine feeding to hyperthyroids immediately after radical operation. Plummer reports (18) the occurrence of no deaths since the establishment of this régime. This test also throws light upon the futility of adding fuel to the flames of a toxic goitre which, as Janney (19) groups it, is a dysfunctioning gland with its consequent faulty hormone. Evidently not all hyperthyroids are dysfunctioning glands—part of them reveal a hypertrophy comparable to the hypertrophy of the overworked heart, and gradually return to normal, clinically, upon the ingestion of available iodine. "The hypertrophy is probably due to strain on a dysfunctioning gland" (19).

To consider for a moment the practicability of attempting to assure a well nourished thyroid by means of supplying additional halogens as an aid to general oxidation and cell activity, Janney has emphasized that "The chief function of the thyroid is the generation and regeneration of the tissues by action of the thyroxin on protein metabolites" (19). As to the origin of thyroxin he says: "All evidence tends to indicate that the thyroid hormone is a synthetic product." Further, "It is certainly built up by the thyroid from inorganic iodine," and so on.

Kendall (20) who first uncovered the active principle of the thyroid elaboration thyroxin, states as to

*Read before the Southwestern Pediatric Society, November 7, 1923, and the Los Angeles County Medical Association, April 17, 1924.

its function that, "By its activity practically every cell in the organism is changed; the effects are felt throughout the nervous system and the circulatory system, the rate of metabolism is enormously increased, and even the skin and hair show revolutionary changes." Again he says: "The function of the glands must be some single chemical reaction which is necessary for the life of the various cells and tissues of the organism."

This "single chemical reaction" product, which Kendall isolated, and now generally known to contain some sixty per cent. iodine, depends upon the ingestion of inorganic iodine as a direct precursor of the elaborated crystalloid iodine of the thyroid, according to researches now clinically accepted. It is superfluous to add that no gland can synthetize its particular product unless sufficient precursors are available. How insufficient in halogen content is our common dietary and how frequently the demands of the present day high tension struggle may exhaust thyroxin reserve, is generally not appreciated.

Accepting the evidence of cellular dependence of the system upon thyroid hormone and noting the effect of insufficient iodine from which this hormone is built, the next logical step is to determine practical ways and means by which the thyroid gland can be adequately fed, and thus restore normal function.

One differentiation in practical application should be borne in mind. Uhlenhuth (21) says: "Inorganic iodine is ineffectual in reactivity of the thyroid hormone, but it is the only substance which can be used by the physiologically active thyroid in the elaboration of thyroxin." To paraphrase, the artificial or natural ingestion of inorganic iodine can be used only as an aid to secure normal physiological function, but not to restore a pathological thyroid gland. Assuming that this premise is true, still it does not detract from the possibilities of farreaching effects upon abnormal conditions which come under the classification of disease, so long as the thyroid gland itself is not diseased. In other words, the formidable group of abnormal symptoms, which are familiar results of hypothyroidism, we may rationally expect to alleviate, provided we administer assimilable halogens to an underfunctioning but not to a patently pathological thyroid gland.

Skinner, of Yakima, Wash. (22), reports congenital goitre caused by iodine deficiency in the mother as rather common. He reports its practical elimination by feeding iodine to pregnant mothers. If it were routine to feed an amount of available iodine approximating half the normal intake of the thyroid during alternate weeks, or in amounts adjusted according to physical and mental condition, or depending upon the special demands made upon the thyroid —if this were routine, there is a rational basis for expecting less ultimate thyroid disorders.

Many symptoms exhibited in children, such as malnutrition, retarded or imperfect dentition, rachitis, asthma, bronchitis and eczema, or revealed in dry skin, cold extremities or multiple adenitis, may be manifestations of subthyroidism which we are accustomed to so group only if definitely showing retarded mentality or marked degenerative stigmata. The clinical picture needs to be clearly defined in one's mind and to be differentiated from that group for which exact laboratory technic is known.

To estimate the existing organic iodine in the circulation is at present too technical, consequently the method of approach must be necessarily different and the possible results will be at times delayed because of this inability to apportion rightly the required elements. But in all apparent physiological imbalance, if, with slight subthyroid manifestations, or if indicated by the usual symptoms, the mental concept of a possible dietetic deficiency be kept clearly in mind and the consequent patience and clinical requirements appreciated, there will be much of satisfaction and not infrequently brilliant corrections which will convince one that the thyroid often needs to be fed. The average amount required in terms of iodine apparently varies in clinical need from one thirtieth to one sixth grain of some nonirritating, stable, inorganic preparation administered once daily, two to five days in each week. The amount is later decreased until finally the indicated quota is determined. This implies physiological balance rather than increasing doses to tolerance as in exhibiting the iodides.

To establish this hypothesis, a perfected blood test making possible the estimation of its iodine content would greatly facilitate its clinical use. Until such test is available, the careful clinical observance of results in indicated cases will produce cumulative evidence. Weight, pulse rate and subjective symptoms must be periodically noted for at least six months.

Before giving case records, a brief résumé of research reports published since the completion of this article, coming from three authoritative sources, seems peculiarly apropos. Their testimony gives added impetus to certain angles in "the hypothesis of a dietetic deficiency" and suggests farreaching possibilities in its correction:

1. Experience at the Mayo Clinic confirms an evident iodine deficiency in hyperthyroids.

2. Harvard Research Laboratory reports the iodine in glandular preparations to be apparently more effective than the extract of the balance of the gland (22) and raises the further question whether thyroxin, isolated, retains all of the physiological action of the real thyroid hormone as normally produced.

3. Rockefeller Research Laboratory reports tumor inoculation experiments in which resistance and immunity were paralleled by an increased physiological function of the thyroid. Increased function implies increased iodine elaboration; this in turn implies necessary availability of thyroxin precursors in our daily food.

TO EPITOMIZE THE HYPOTHESIS IN BRIEF

1. Federal Geological Survey of iodine bearing soils and waters reveal vast areas depleted of their original halogen deposits.

2. Areas in which this deficiency is most complete, correspond to the socalled goitre belts, in other words, diseased thyroids accompany deficient iodine.

3. Not alone definite disease of the thyroid but multiple complexes dependent upon dysfunctioning thyroids arise through this halogen deficiency.

4. This gradually increasing hyperplasia of all thyroid glands receiving insufficient iodine, not only produces ultimate destruction of the gland function,

but during this period of its lessened activity allows a disturbed physiological balance which opens the door to active invasion. This invasion may cause the host to succumb by ceasing to inhibit activity of embryonic rests, may cause him to be overwhelmed by acute bacterial invasion or merely allow him to drop far below his normal level physically and mentally.

5. Consequently the physiological balance of this halogen deficiency requires essentially a food for the thyroid gland, not adequately found in our modern diet.

6. Laboratory tests in animals apparently confirm this hypothesis.

CASE REPORTS

Case I.—*Type with no functioning thyroid gland. (Cretinism.)*—A. K., aged twenty-six months, female, Hebrew, family history negative, labor at term, uneventful. The child's development attracted no attention until six months, when she was taken to Dr. G., New York, for examination and a diagnosis of cretinism resulted. The child thrived under usual thyroid administration, and when referred to me at the age of eighteen months, was developing satisfactorily.

Inorganic iodine was administered and the substitutive thyroid extract was withdrawn to determine if true cretinism existed. During this period of thirty days, the child gained two and a half pounds, grew pale and flabby, while the facies assumed the characteristic appearance of the cretin. Stupidity was evident.

A return to the organic extract produced a rapid amelioration of all symptoms, sufficient to indicate continuous substitutive therapy and the inability of the child's glandular system to elaborate its own thyroxin. X ray report: "Sella turcica considerably larger than normal anteriorly and with hypertrophy of both anterior and posterior clinoids."

Case II.—*Type with underfunctioning thyroid gland and inability to attain balance through ingestion of thyroid extract. (Cretinoid.)*—F. C., aged seven and a half years, female, Hebrew, family history negative. The child lacked ambition, was tired and had an indifferent appetite, disposition was listless. The child showed no desire to play with nor meet other children. The mother's complaint was of the child's color—unhealthy tan with yellowish tinge around hair of forehead and pallor around mouth and nostrils. Examination revealed weight four pounds over the average, eyes dull, skin and hair and nails dry, muscles flabby moderate postcervical glandular enlargement, lips slightly pale, tongue coated, tonsils enucleated at three years. Nasopharynx revealed mucus discharge, ears negative. Pronation with beginning valgus of both feet was noted. A metabolic test was not made. Orthopedic shoes relieved foot strain, correction was made of diet and hygiene, tonic doses of thyroid extract were given. During the subsequent two years the child made fitful progress, exhibiting cumulative effects apparently from thyroid ingestion or glandular impurities included in the dried tablets. Finally carefully tried out amounts of inorganic iodine were administered with the almost immediate result of a beginning restoration to normal which terminated in evident health as indicated by skin, membranes, secretions and activity. The mother's comments emphasize the child's improved condition of hair and skin with the remark upon activity that, "Now F. climbs trees." The child seems in perfect health merely from ingestion of a sufficient amount of iodine for her underfunctioning thyroid gland to produce sufficient thyroxin. Unlike the patient in Case I, this child seemed absolutely unable to assimilate a substitutive thyroid product yet exhibited the clinical picture of hypothyroidism.

Case III.—*Nervous instability.*—M. L., aged seven and a half years, female. The mother, who was of more than average intelligence, reported that for the past two years spells or temporary loss of consciousness had occurred at approximately monthly intervals and that the child's reports from school had been correspondingly less favorable. History and examination revealed no factors of importance except that the family dietary included insufficient halogens and minerals with their possible bearing upon this evident nervous instability. Two other children in the family, however, suffered no apparent lack, nor did they exhibit nervous instability upon a similar diet. After two months, during which an attempt had been made to equalize possible salt and mineral requirements, there resulted absolute freedom from nervous imbalance and her school reports were the best of the three children. To this date after eleven and a half months, no break has occurred in her restoration to an apparently perfect balance. No sedative nor drugs were administered.

As a corollary to this case—it has been stated that "two other children in the family suffered no apparent lack. A brother two years older with a pulse rate of one hundred had infected tonsils enucleated and adenoids removed without affecting the pulse rate after a three months' interval. The temperature was normal. Effect of iodine administration will be noted after corresponding interval which has not yet elapsed.

Case IV.—*Functional hyperthyroidism.*—C. G., aged fifteen years, male. The child's mother had a goitrous tendency, revealing slight enlargement but no associated symptoms. The patient had had measles at five years, fracture of humerus at thirteen years, whooping cough at fourteen years. Temperament sanguine with superior artistic and musical ability. Sleep easily disturbed and difficulty in getting to sleep. Sea foods were not available on account of inland residence.

Physical examination revealed height of a child of sixteen with weight fifteen pounds below average for that height. Body type slight but with chest expansion of two and a half inches. Vital capacity was normal at 2300 c. c., blood picture normal, systolic pressure slightly subnormal, a thyroid gland slightly hypertrophied in right lobe. There was superior mental activity. The pulse rate was 102. There was an inability to gain weight normally. Occasional attacks of nervous indigestion, apparently the symptom complex of a dysfunctioning thyroid gland.

Until recently the simple expedient of furnishing available material for additional thyroxin elaboration had not seemed a rational procedure. Under administration of one tenth grain daily alternate weeks for six weeks he made greater weight gains and slept

better during the iodine weeks, his pulse came down to 90, and his weight increased four pounds six ounces during that period. An apparent result of correcting the physiological deficiency in halogen bearing foods.

Treatment of Pruritus Vulvae.—P. Werner (*Wiener klinische Wochenschrift,* March 27, 1924) believes in the endocrine origin of pruritus vulvæ, especially in the influence of the ovaries. Röntgenotherapy, on the whole, has been disappointing. Observations show that the pruritus is more or less intimately associated with the climacterium and pregnancy and the menstrual periods. Treatment should be directed toward the endocrine system. The occasionally good results obtained with local x ray therapy may be due to simultaneous action on the ovaries. The treatment consists in the administration of ovarian gland substance as injections over a long time. Good results may also be obtained with x ray treatment of the ovaries and hypophysis. Irradiation of the thyroid gland seems to be futile.

Treatment of Pruritus Vulvae.—S. Wiener (*Surgery, Gynecology, and Obstetrics,* December, 1923) offers a new treatment for this condition, based upon the belief that the itching is due to an irritation of the nerve endings, and that the consequent scratching gives rise to a vicious circle of cause and effect which must be broken into to effect a cure. The treatment follows:

The technic employed is very simple. The skin and subcutaneous tissue along the outer border of the labia majora are continuously infiltrated with a one per cent. solution of novocaine. Eight cubic centimetres are used at one sitting, four cubic centimetres being injected on either side of the vulva. No curative effect is attributed to the novocaine. Its purpose is merely to render the infiltration itself painless. The curative action is attributed rather to the mechanical effect of the infiltration, and could doubtless be achieved, though in a less painless way, with salt solution. All cases have been readily treated in the out patient department. The injections have been repeated at intervals of a week. No patient has received more than five injections; in some patients from one to three have sufficed. The results have been distinctly encouraging.

Effect of X Rays on Leucemia.—As a result of his investigations Paul Szilárd (*Wiener Archiv für innere Medizin,* April 1, 1924) comes to the conclusion that the cause of the socalled secondary effect of the roentgen rays may be attributed to the fact that the electric charges, the electrons, which penetrate the body during the irradiation from the tube and circulating in the blood stream, reach every part of the organism and also exert their destructive influence upon distant and not directly irradiated sensitive tissues and organs. There was a slightly more active destruction of normal leucocytes by the serum from leucemic patients than with normal serum. The leucemic cells were destroyed much more readily than normal cells by any other serum.

Intravenous Injections of Urotropin Solution (Forty Per Cent.) in Postoperative Urinary Retention and Cystitis.—C. Pasch (*Zentralblatt für Gynäkologie,* March 29, 1924) obtained some very good results with intravenous injections of forty per cent. urotropin solution in the prophylaxis of postoperative ischuria and cystitis. This form of prophylaxis was applied in minor and major gynecological operations, both vaginal and abdominal, and also in protracted labor and after obstertical operations. The usual dose is three to five c. c. The indications are postoperative urinary retention or ischuria several days after operation. Improvement is seen after two to ten hours. This procedure avoids the use of the catheter and subsequent bladder infection. Cystitis due to the colon bacillus responds readily to this treatment. For prophylactic purposes the injection should be given three to four hours after the operation. No ill effects were observed.

Curative Dose of Antimony Tartrate in Schistosomiasis (Bilharzia Disease).—J. B. Christopherson (*British Medical Journal,* December 29, 1923) asserts that thirty grains of antimony tartrate, administered over a period of twenty-eight to thirty days, remains the curative dose of schistosomiasis for an adult. Cases of long standing may require a modified second course of thirty grains. The fact that the symptoms have cleared up and no ova (or no live ova) are found in the urine is in itself no indication to suspend injections until the full dose has been given. Antimony tartrate commences to stop the ova appearing in the urine at about five grains. At ten grains some of the ova which appear in the urine are dead. This drug acts on the ovum (the motor mechanism) first, and also affects the worm so as to suspend its egg producing activities; but the worm is not killed till later—if too little antimony is given it recovers and recommences egg laying, and hence a relapse takes place after an apparent cure.

Historical Medicine

Hippocratic Nephritis

JONATHAN WRIGHT, M.D.,
Pleasantville, N. Y.

Having been betrayed into a study of Hippocratic and præ-Hippocratic anatomy of the kidneys and into some citation of Aristotle's statements on the subject by an interest in the curious belief, which prevailed in and before the time of Hippocrates, that fluids when swallowed passed into the lungs, I have incidentally made notes of what the Hippocratic authors have to say of kidney disease. This it may not be devoid of interest to have arranged in some attempt at sequence here.

The modern conception of kidney disease so largely centres around the problem of metabolism, it is so closely affiliated with systemic and general circulatory disturbances, the biochemistry of the subject has so alienated our ideas even from those of a generation or so ago, that we have no cause to be surprised in finding the Hippocratic conception is almost exclusively a surgical one. The chief interest centres around stone in the kidney, so frequently associated with the symptoms also of stone in the bladder. It is singular, but indicative of the very ancient interdict laid on those who practised medicine not to cut for stone, that no word is said on this subject while the advice is frequently given to cut for kidney abscess caused by kidney stone. We may well be astonished how boldly the Hippocratic surgeon is advised to make deep incisions for the relief of this condition. It impresses us with the feeling how disastrous it was to confine an operation for the removal of stone in the bladder, offering such prompt and ready relief from suffering, to persons unskilled in the art of medicine. There is no satisfactory explanation why this operation had so moved the distrust and suspicion of ancient men as to cause its prohibition to be included in the medical oath. Nothing so arbitrarily and so unjustly has interfered with the exercise of surgery except the superstition which tabooed dissection of the human structure.

Scarcely less interest is manifested in uroscopy as a prognostic and diagnostic resource in other than kidney affections: "When there is a farinaceous sediment in the urine it indicates a protracted illness (1), but when the urine is thin at first and then the sediment becomes bilious acute disease is indicated (2). When the bubbles settle on the surface they indicate disease of the kidney (3), so also of a fatty scum" (4) and much more which is Greek or foolishness to us. But that the ancient profession was alive to the opportunities of this kind, open even to them unaided by our science and our scientific apparatus, an author, perhaps a sophist layman, writing of *The Art* (5) declares, saying: "It judges of the secretions by their odor, color, consistency, and from these draws conclusions as to the conditions of which these are the signs, some showing a place already diseased, some those which are liable to be attacked." In the Coan Prænotions, from which doubtless some of the aphorisms were directly or indirectly culled, we find this art in full bloom and the Coan Prænotions, all agree, were older than Hippocrates II. For thousands of years uroscopy was an important part of diagnostic observation, probably ever since man used a vessel into which he passed his urine. Constant examination of this even by his unaided senses and comparing it with the patient's state we may well believe brought an acuity of recognition we have long since lost owing to our neglect of naked eye diagnosis for the more profitable one of the test tube and the microscope. It was like the pulse; the ancients could see things in the urine with their eyes as they could feel things in the pulse which with our bare fingers we can not. The modern scoffer may shrug his shoulders and add contemptuously, "thought they could," but we too "see things" in the test tube and the sphygmograph and *The Art* in those days was probably no more of a gesture than it is today. It is still said to be an art—not a science.

None of us will venture to say these sententious prognostications in any age are always justified by the event, but with the tactile sense for the quiver of the pulse gone we have also lost their solution of the mysteries that float in the urine. The new uroscopy is not infallible and with the passing of the old uroscopy we have lost that skill, such as it was, of the ancients, those men as acute minded as we, who found wisdom in the Coan Prænotions, the oldest of all our records, which helped them. It still may be made to flash for us and we see the flash of the old diagnostician, whoever he was who wrote: "Patients who only void their urine when told to are in great danger" (6) and we know how true is the aphorism (7) "Nephritis as well as cystitis is difficult to cure in the old." We see, too, that the Coan practitioner knew well that suppression of urine is apt to have as a sequel headache and some times spasms (8). He knew, too, the cure is difficult but the case is not necessarily fatal. He knew, too, the suppression of urine in this case is to be differentiated from that caused by stone or thickened urine (9). We get clear indications of renal complications which make the severer forms of malarial fever so dangerous. "When, after the urine has had a good sediment it has none, there is an indication of a painful change and the urine having as a sediment a troubled deposit points to a chill near a crisis and a change to a tertian or quartan fever" (10). Relating elsewhere (11) a case an author remarks in a tertian fever after several months there was a complication with the kidneys which persisted, this diagnosis, so far as appears, being based upon pain in the lumbar region. There are clearer indications elsewhere (12) and in a way the varieties of kidney disease are discussed. In the Hippocratic as well as in the Galenic physiology the black bile originates in the spleen. Besides the kinds the pains represent there is a third in which the urine, accord-

ing to the observer, looks like the juice of beef. Blackwater fever is still a doubtful disease variety of malarial regions and here we are left still more in doubt as to the diagnosis, but as he advises putting the patient for forty-five days on a diet of milk and whey, we seem justified in thinking of the severe and dangerous fevers of the swamps of the Congo and the Amazon, occurring here around the Mediterranean in the time of Hippocrates.

In a fourth variety (13), which he believes is due to excessive coitus, besides lumbar pains, the urinary sediment is sometimes white and sometimes bile colored, but when the patient lies on the unaffected side he experiences discomfort and pain. Possibly this was a case of enlarged spleen, but that hardly meets all the indications of the history.

More acute disease is possibly betrayed in the aphorism: "Whenever in a thick urine there are small flesh like hairs, these are cast off by the kidney," but when there are thick scales in the urine he thinks these are due to scabies or psoriasis of the bladder (14).

Notwithstanding these indications of kidney involvement in the general circulatory affections with which we now connect it and its complication of other diseases and even a hint of a comprehension of disease which is neither a complication nor a surgical affection, the most stress is laid upon the phenomena of kidney stone and abscess. If the patient passes pus and blood in the urine, this indicates ulceration of the kidney and bladder and whenever blood spontaneously appears in the urine it signifies the rupture of a vein in the kidneys. If he passes clots in the urine and has strangury and pain invades the hypogastrium and perineum he has trouble around the bladder. In various aphorisms (15) these and other signs of inflammation and neoplasm are recorded, and in the book on *Generation* (16) we may suspect gonorrhea in those exercising coitus who have blood in the semen. The Hippocratic author, however, ascribed this to ulceration of the kidneys.

"But whoever has sandlike sediment in their urine these have stone in the bladder." This classical indication of stone in the bladder as set forth in the Aphorisms (17) is repeated in various places, in various ways, but in the *Internal Affections* we have the subjective signs set forth (18) of stone in the kidney. Sharp pain in the region of the kidney and in the perineum and flank and in the testicle of the affected side, frequent micturition, with gradual diminution of the urine which becomes sandy, intermittent and thick. There is severe pain in the urethra as the sand passes, relieved when the urination is over, but aside from this pain affects the penal part of the urethra." Many physicians familiar with the disease, when they see the sand in the urine think the stone is in the bladder but it is not, it is in the kidney. "This disease arises from the phlegm. Whenever the kidney receives the phlegm and does not discharge it, it collects within it. This becomes like gravel."

As for the treatment, the diet is to be regulated. Warm baths and hot fomentations are to be used for the pain. The patient was recommended to drink a quart or more of salted pea soup or white bean soup. But if a swelling occurred—cut down over the kidney and let out the pus and use diuretics to get rid of the sediment. If you don't use the knife the patient will die. This is the first of the kidney diseases mentioned in the *Internal Affections*.

The second kind of disease of the kidney seems to have been an abscess starting with a hemorrhage from the vein of the kidney itself, resulting in ulceration of both. Again the advice is to cut down on the kidney and the result will be good if you strike pus and bad if you do not, leaving an unhealed wound. Then the patient is liable to die.

Fig. 1.—The science of uroscopy. Fig. 2.—The reward of charlatanry.
(*From Peter's Arzt und Heilkunde*)

It is impossible to identify the pathological conditions on which some even of the striking symptoms depend. "Those in whose urethra caruncles grow and suppurate and break off and appear in the urine" (19) may have suffered from papillary tumors of the bladder. It is also not at all clear it was a case of kidney disease the author had in mind in the interesting account given of the régime to be applied to the man overfed and under exercised or it may be that in this condition the author recognizes a fertile cause for what used to be called idiopathic nephritis. Shortly it is this. Divide his customary food into ten parts. The first day deprive him of one part and make him walk ten stadia (somewhat over a mile). Next day, take away two parts of his food and make him walk twenty stadia, and so on until the man is down to one tenth of his usual food and is walking more than ten miles a day. Then increase his daily nourishment and shorten his physical exertions by the same gradations until the bon vivant is allowed to celebrate the termination of his discipline by an hilarious banquet (13). This was the way to get the man of Athens or Corinth fit, but the

modern health moralist has a right to demur at the high flier being led by as gentle steps back to his full trough as those by which he was made to depart from it. There are signs that this system of regimentation has been applied without much discrimination in the recommendations for the after treatment of severe surgical kidney trouble. Apparently it is here a clumsy interpolation. For a convalescent it is little short of grotesque, but with some modification of the return journey to gourmandizing it seems a method not altogether dissimilar to some of our training camps for the over fed. It has features decidedly improvements on the course pursued in some of them. The gradual elimination of the intake and cautious increase in the exercise is not always a prominent enough feature in our modern outdoor gymnasia.

Contributors to the Science of Medicine

Chervin, a Pioneer Epidemiologist

WILLIAM COLBY RUCKER, M.S., M.D.

New Orleans, Louisiana

For almost forty years there has been hidden away in an iron box in the Army Medical Library, at Washington, a pile of priceless manuscript. Through the courtesy of the librarian, Brigadier General Robert E. Noble, and the kindness of Mr. Felix Neumann, who brought it to his attention, the writer has been afforded access to this collection, which represents about five years of earnest epidemiological research, and one of the earliest applications of the questionnaire to the study of pestilence.

Nicolas Chervin was born of agricultural parents, at Saint-Laurent-d'Oigt (Rhone), October 6, 1783, and, after pursuing his preliminary studies in the College of Ville de Franche, chose for himself the profession of Commerce. His parents consenting in his choice, he went to Lyon with a letter of recommendation which has been given him by M. Fournas, the father in law of the celebrated artist, Ellevain. After he had presented his letter, he went with one of his fellow pupils, named Petit, a student of medicine, to attend a lecture on anatomy which was being given by Professor M. Montain, and by this unthoughted act his entire life career was altered. The lecture was upon the sphenoid, the keystone of the cranium, one of the most bizarre bones in the entire human framework and at the same time one of the most difficult of description, but Montain's recital was so clear, so methodical, and at the same time so finished that Chervin was struck with admiration. It had never before occurred to him that any part of the human body could be so interesting, so wonderful.

For a few days he was depressed and undecided as to what course to take; but, says Rougier, "to use an expression of a religious sect, he felt the impulse of the medical spirit and consecrated his body and mind to the study of our art."

Chervin was a man of energy,and having seen the way, he set out to follow a resolution which he kept to the end of his days, never faltering in his thirst for medical knowledge. He enrolled himself as a student of the Hotel Dieu of Lyon, and there he followed, with that painstaking exactitude which was one of his characteristics, the curriculum of that great institution. Later he went to Paris, where he received his doctorate in 1812. He chose for his thesis a curious title: *Medicophilosophic Researches into the Causes of Polygamy in Warm Countries,* in which he controverted the theory that this practice was due to the excess in the number of women in the tropics. At this time France was in throes of the Napoleonic epoch; the empire was being attacked on every hand, and the homeland was menaced with invasion. Not only was the army of France being killed by the bullets of the enemy, its soldiers were being decimated by typhus fever, which was then prevalent in most of the military hospitals. The Government sent many young physicians to the epidemic centres for the purpose of studying the disease and assisting in the treatment of the infected. Chervin was appointed a member of the commission which went to Mayence, a location in which typhus fever was spreading with extreme violence.

Upon the declaration of peace, Chervin returned to Paris, where he entered practice, devoting one or

two days a week to clinical studies in the hospitals: and again a small circumstance altered his plans and directed the current of his life into another channel. He was in the habit of lunching with several of his friends, physicians who were pursuing their clinical studies in the hospitals. One day the conversation in this informal lunch club turned upon the question of whether or not yellow fever was contagious. Many of those present believed that it was, and one of his friends expressed himself very strongly in this belief. Chervin, who was possessed of a healthy, scientific skepticism, said he was not at all convinced that yellow fever was contagious. "But do you know that?" queried he of the strong affirmative opinion. "I am going to prove it," said Chervin. "But not on the banks of the Seine," was the reply.

With characteristic promptness and decision, Chervin sold a part of his patrimony, and with the little money thus acquired, but an enormous fund of courage, patience and energy, he set out upon his quest. Unfortunately, a journal of these wanderings is not included in the pile of manuscript at the Army Medical Library, but it has been possible to map out more or less accurately a part of his itinerary from these documents.

Apparently he first visited Guadeloupe; on November 24, 1817, he was at Pointe-Pitre, and on the 30th he was at Basse-Terre—a curious coincidence, this, since the latter was the birthplace of Louis-Daniel Beauperthuy, who on May 23, 1854, in the official gazette of Cumaná, Venezuela, announced the discovery that the mosquito with white striped legs is the vector of yellow fever. Beauperthuy was born at Basse-Terre August 25, 1808, and he was therefore a little over nine years old at the time of Chervin's visit to Guadeloupe. It is not inconceivable that the presence of such a distinguished foreigner as Chervin, in such a small place as Basse-Terre, was known to Beauperthuy, and his boyish mind thereby imbued in some degree with the desire to take up scientific research, a field in which this great medical naturalist was to achieve posthumous renown.

The next year, 1818, was devoted to wandering up and down the Antilles and the other islands of the Caribbean, Martinique, Antigua, Nevis (the birthplace of Alexander Hamilton), Montserrat, St. Kitts, St. Eustatius, St. Martin, St. Thomas, St. Croix, Barbados, Porto Rico, Santo Domingo and Jamaica being visited. In 1819 he was in Cuba and Haiti, and on March 1, 1820 he is found at New Orleans, La., where he remains at least three months. In November he is in Savannah, Ga., and from December 20, 1920 to January 9, 1821, he is in Charleston, S. C. March, 1821, finds him in Norfolk, Va., and Washington, D. C.; in April in Baltimore; in May and June in Philadelphia; and in November in New York. Connecticut, Rhode Island, Portland, Me., Newbury Point, Mass., and New Hampshire, were visited in the last month of that year. Then he returned to the Islands of the Sea, and the latest date in the manuscripts is in August 1822.

Wherever he went he examined everything in the locality which might have a bearing on the epidemiology of yellow fever. He studied the climate, the seasons, the habits of the people, and their customs. He visited the hospitals, he attended the sick, and studied the effect of disease as shown in the bodies of those who had died from it. He interrogated physicians, army medical officers, navy medical officers, quarantine officials, hospital superintendents, magistrates, and the inhabitants of every class, including the negroes and slaves. All of this labor was performed most minutely; he was scrupulously methodical in the collection of his data. To each of the medical men whom he interviewed, he gave the following questionnaire:

QUESTIONNAIRE

Avez vous observe des faits, que provenent, que le fievre jaune soit contagieuse?

Pensez vous, qu' deprimer le devenir dans certaines circonstances?

Quelles sont, suivant vous, les causes le plus ordinaires de cette maladie?

Pensez vous qu' une meme personne peut-etre ataquée, plusiers fois de cette maladie?

The replies to which were written on sheets of paper ten by twelve inches, and before he left the place where he had collected them they were bound together by colord silk ribbons which were passed through three holes in the left hand edge. These were then certified as authentic documents by some person having legal authority to make such certificates. Sometimes it was a British Governor General, and in one instance the seal is a circular piece of wax over two inches in diametre, having a sheet of paper on either side, and being embossed with the royal arms of Britain. Frequently there was a certificate from the president of the medical society, stating that certain physicians were members in good standing. The certificates taken at Washington, D. C., were certified to by the French Ambassador, Baron de Neuville. Thus there is preserved in this collection the authenticated signatures of many of the leading medical men of the new world at that time.

These documents are exceedingly interesting. Physicians tell their experiences in certain outbreaks of yellow fever, and they relate many circumstances which would be of the greatest value to anyone who was collecting the material for a biography. For the most part, the handwriting is beautifully clear. There were no typewriters in those days, and people apparently had more time; certainly, they took more pains with their chirography; as a result, the reading of these manuscripts is relatively easy, and also there is a thrill in almost every page. They are written in English, French, Spanish and Dutch. Apparently Chervin mastered the English language in the course of his investigation; there are many notes in his handwriting written in that language: for example, when he was in New York he copied a great many of the minutes of the City Board of Health.

In the learning of English, Chervin pursued the accurate, painstaking course which may be observed in all of the acts of his life. There is a list of about 275 words and phrases which he has collected under the title: *"Liste de mots anglais peu usités ou plutôt qui me sont peu familiers."* A perusal of these shows that he had gotten well beneath the skin of the American tongue. The following excerpts, spelled exactly as they are in the little folio, illustrate this:

Hey; to jog on; tucked up; hawked about; to bantter;
with a hop, skip and a jump; fiddle faddle, topsy turvey;
rapping of kuckles; plung down the money; wen-goitre;
to hum and haw; a lucky hit.

Although Chervin examined hundreds of patients in hospitals, made observations on their condition both by day and by night, being exposed to the black vomit and other dejections, attending necropsies, and being in every way in the presence of the contagion, if such existed, he never contracted the disease. In this he was a good deal more fortunate than that celebrated Italian epidemiologist, Eusebio V. Valli, who came to Havana for the purpose of studying yellow fever. He landed on September 7, 1816, and on the 24th of the same month was dead of the disease.

An analytical study has not been made of the data which was obtained by Chervin in the Caribbean littoral. At a later date this will be done. Practically every one of the physicians whom he interviewed in the United States was of the opinion that the disease is not contagious—that is, that it is not spread from a sick person to a healthy one by contact. They frequently note the fact that while doctors, nurses, attendants, ministers, sextons, and the families of those who have yellow fever, were not more liable to the disease than other persons, and from this they reasoned very properly, that the disease was spread by some other agency than intimate contact. The introduction by ships was carefully noted, especially by quarantine officers or Health Officers of the Port, as they were called in that day, but Pardon Brownell of Providence, Rhode Island, wrote on December 10, 1821, that he did not believe that the disease was introduced by ships from foreign ports, but was generated by them.

The minds of some of the physicians were evidently still impressed by "the unity of fevers," but a considerable number make the differentiation between yellow fever and bilious fevers very clearly. For example, William Bowen, of Providence, Rhode Island, writing on December 12, 1821, of the outbreak of typhus icterus of August 1787, said, "I judged it as a higher grade of our common Summer or bilious fever from which, however, it is essentially different, the one being but partially, if at all, mitigated, while the other is totally suspended by Frost." There is little accurate differentiation between yellow fever and malaria, some thinking that they are merely different manifestations of the same disease, but several beliving that they are separate and distinct infections. Several speak of having had yellow fever themselves, and the clinical descriptions of the disease set forth in the replies to the questionnaire, prove very clearly that although the writers had relatively little knowledge of epidemiology, they were exceedingly keen clinical observers.

The cause of yellow fever is variously attributed, many holding that it is a disease of purely "domestic origin," "calmness of the air and decomposition of animal and vegetable matter"; "effluvia from ballast"; "decomposing codfish and the noxious effluvia therefrom"; "the pestilential atmosphere engendered on ships"; all being named as etiological agents. William Ingalls of Boston wrote a long letter (including a meterorological table), saying, "Yellow fever is not generated at sea or far inland." He expresses the view that effluvia and sea water raised by hurricanes into the air, mix and produce a dangerous stimulant. The action of the "vertical rays on the sun on odure" is frequently mentioned in these letters.

Josephus W. S. O'Conway, U. S. N., writing on May 8, 1820, describes an outbreak which occurred on the U. S. Schooner "Firebrand" at Belize in July 1817, and states, "The vessel was almost alive with cockroaches, their scent was suffocating, and all our provisions smelt of it. This is a strong proof of vitiated atmosphere."

H. R. Frost of Charleston, South Carolina, in his letter of January 3, 1821, expresses the opinion that yellow fever, which he believed is not a disease suis generis, is due to the "mephitic gases, produced by the vertical rays of the sun, this in turn causing a deficiency of the atmospheric electricity." In a rather hasty survey of the material, mosquitoes were only seen to be mentioned once, and that in such a way as to show that the writer had no idea whatsoever of their possible connection with the disease. It was noted by quite a number of observers that certain areas seem to be immune to the disease, and one writer quotes an observation made in 1809, "that those who slept in the upper stories of houses were less liable to the disease, and had it in milder form, than those who slept on the ground floors."

Dr. George Marshall of New Orleans, writing under date of March 26, 1820, sets forth some views of the etiology of the disease, which are interesting in the light of our present knowledge. At the time he was secretary of the New Orleans Medical Society. In 1812, he had charge of the U. S. Naval Hospital, temporarily established in the Bay of St. Louis and in 1813 he was attached to the U. S. S. *Louisiana*. He says:

> Domestic animals and those of the Forest are frequently affected with a variety of disease during the prevalence of an epidemic, and even the vegetable Kingdom does not always escape unhurt. The following is an extract of a letter from my friend, Dr. Perlee of Natchez, in October, 1819: "As to the report of our domestic animals dying, it is partially true. Our horses, horned cattle, poultry, and even the Deer in the woods, have been very generally affected with a disease seated in the tongue. It has not been very fatal except to poultry on some plantations, but as respects human sufferings we have indeed had a severe visitation."

Strangely enough, there are still a few sanitarians who believe that animals may act as a reservoir for the infection of yellow fever.

Having completed his researches in the new world, Chervin returned to Paris, where he took a modest little room in the Rue Villedo. From all accounts, he was not prosperous, and lived in his scantily furnished rooms, surrounded by his books and the documents which he had secured in his epidemiological quest. But he was scarcely settled in this apartment in which he was to live for many years, before he learned that yellow fever was epidemic in Spain. He hurried there to carry on his studies, going to Cadiz with Louis and Trousseau, as a member of a

commission appointed by France to study the epidemic of yellow fever, then prevailing. He carried on further studies in the Midi and on the Peninsula, and from there went to Barcelona, where other French investigators had succumbed to yellow fever.

In 1824 Chervin returned to Paris, with the intention of staying there only six months, but he remained for nineteen years, excepting when he went to Gibraltar in 1828, again to study yellow fever. Upon his return, he was decorated with the Legion of Honor. His name was then presented for membership in the Academy of Medicine. Unfortunately, the permanent secretary of that body, Ettiene Pariset, an epidemiologist who had made a considerable study of miliary fever, yellow fever and plague, belonged to the contagionist school, so far as yellow fever was concerned, and as early as 1828 he and Chervin had a controversy over the latter's conclusions with regard to yellow fever. These were:

1. Yellow fever is not contagious.
2. It has for its origin and cause the altered air of swamps, obstructed drains, and the exhalation arising from slimy stagnant waters.
3. It acquires its greatest violence by the excessive heat inherent to certain climates and certain seasons.
4. Lazarets and quarantines which are onerous for governments and prejudicial to commerce, neither serve to prevent, nor to lessen the violence of the infection.

Pariset's divergence from these views caused Chervin's name to be subjected to critical examination when he was proposed for membership in the Academy, but a commission of eighteen members having examined his documents, declared unanimously that they were of great value, and proved conclusively the noncontagiousness of yellow fever. This report provoked a long discussion in the Academy, but in 1832 Chervin was elected to membership. A few years later he received from the Academy of Science a prize of ten thousand francs from the Montyon Foundation. Finally, the campaign of education which Chervin launched had its effect, and the Government, by the ordinances of April 4 and June 11, 1835, and November 13, 1839, modified its sanitary regulations with regard to quarantine, and reduced the period of detention of ships very considerably.

The latter years of Chervin was not happy ones; sickness, age and poverty beset him. He was afflicted with heart disease, and on February 8, 1842, he suffered from a cerebral hemorrhage which produced hemiplegia; on August 14, 1843 he died at Bourbonne-les-Bains, whither he had gone in search of relief. His friends chose for his epitaph a passage from Tacitus: *"Opum contemptor, recti pervicax, constans adversus metus."* By his life, and by his ability to work, Chervin justified this portrait.

Measured by the terms of modern knowledge, Chervin's was a life of lost endeavor. He made no basic discoveries, and his writings did not contribute greatly to the sum of human knowledge. He did, however, set an example of painstaking, methodical, scientific research, in an era when men were more apt to theorize about a disease, than to study it on the ground. Success is not always the criterion of the worth of a man; endeavor, rather, is the standard: and the courageous, unending effort which Chervin put into his work, entitles him to great credit. To the medical profession of America, he has left a splendid heritage in the manuscripts which were prepared by the leading physicians of our country more than one hundred years ago, and the student of medical history and medical biography will there find authenticated documents of the greatest value and interest.

The Growth of Psychotherapy and the Evolution of Psychoanalysis.—Dr. Albert Polon writes (*Mental Hygiene,* January, 1924) that psychotherapy is of very ancient origin, dating back to the dawn of civilization. "Not unlike religion, it represents one of the most universal products of the human mind. On all levels of culture, at all times and among all peoples, it is found to play an important rôle in alleviating suffering. For primitive man, it represented practically the whole of his therapeutic armamentarium, based upon the notion that disease is an invasion of the body by some malevolent spirit, which accordingly must be driven out by spiritual means, such as magic or religious procedure. In antiquity it came to be separated from actual treatment by being accorded a place as a preparation or as a stage preliminary to the application of medical measures. . . . This character it retained throughout medieval times, when religious faith was regarded as indispensable for the efficacy of surgical and medical measures."

In the early part of the modern epoch (sixteenth century), there was an increasing recognition of the importance of the imagination in curative procedures. The emphasis, however, was upon the special powers of the therapist, from whom presumably the therapeutic influence emanated. This belief was the basis of Paracelsus's "personal magnetism" and of mesmerism. The element of charlatanism in Mesmer's work tended to repel science, and so much that might have been valuable in his discoveries was not utilized for many decades.

Psychotherapy as a scientific procedure is a comparatively recent arrival among the medical branches. Its beginning probably dates from Charcot's application of hypnotism to the removal as well as to the production of hysterical phenomena. Charcot's pupil, Pierre Janet, established the mechanism of dissociation of the personality, but progress remained blocked by the still prevalent notion that hysteria was a defective state of the brain.

The next notable advance was made by Bernheim of the Nancy school, who came to the conclusion that the whole phenomenon of mind influence is entirely the result of suggestion. In 1893, Breuer's report of the case of Fräulein Anna was published, with its light on the procedure of emotional catharsis. This procedure was elaborated by Freud, who had been a pupil of Charcot and Bernheim, and the theory of the sexual origin of neuroses was added. Freud also substituted the socalled association method for the emotional catharsis, and later the free association method, which step marked the abandonment of hypnotism by the Viennese school of psychotherapy and laid the foundation for the psychoanalytical method.

Editorial Articles

THE PERIL OF PUDDING

More than one distinguished authority on diet has declaimed from the housetops against the food of civilized communities and especially against the diet of the growing child. Not the least celebrated of these is Dr. Harry Campbell, of London, who has persistently preached the doctrine that the food of civilized human beings, and of the younger generation in particular, is not adapted to its necessities or needs. Not only is it lacking in constituents and elements essential to sound health but its consistency is also gravely at fault. The ideal diet should be of a quality adapted to the life led by the individual.

The out of door manual worker is able to digest and assimilate, not alone with impunity, but with advantage to himself, a bulk of food material which would be disastrous to the sedentary worker and the one who does most of his toil with his brains. The manual worker and he who spends the greater part of his time in exercise in the open air can consume and benefit by much larger quantities of meat protein material and carbohydrates than the person who lives chiefly indoors.

Climate again plays a prominent part in the selection of a suitable diet. However, these are points which if not so frequently heeded as they should be, are more or less known to all. The question for discussion here is the ordinary diet of civilized people of the English speaking race under ordinary conditions.

Dr. Harry Campbell, a modern Don Quixote perhaps in this respect, never misses the opportunity to tilt against the windmills of custom as regards modern diet, and his strictures apply even more forcibly to this country than to Great Britain. He inveighs in no measured although in strictly scientific terms against the habits of eating of the older and especially of the young generation of these days, the soft stodgy food, made largely from grain which has been deprived of its outer covering containing the vitamines and other valuable elements.

This often predigested food affords no exercise for the teeth and jaws, which they were obviously intended for, with the consequence that they lose their powers through lack of use. Moreover, the digestive functions tend to become lax and slow and even aborted because there is no call for their activity. Thus the food material arrives in the intestines in a condition of comparative inertness greatly aggravated by the fact that on account of there being little or no rough material in the food there is also weak peristaltic action, and chronic constipation and chronic intestinal stasis ensue. This preponderance of soft food is injurious, too, to the teeth themselves, lodging itself in the interstices, and is a factor in the production of caries and possibly of pyorrhea alveolaris.

In this country the huge consumption of candy and saccharine material by adults as well as children may be characterized as a distinct menace to health. The eating of candy to excess by children is a fertile, perhaps the most fertile, cause of teeth decay and is harmful to the digestive functions and to the gastrointestinal tract generally. The undue consumption of pappy food and of saccharine matter sets up or increases a vicious circle. The gastrointestinal tract falls into disorder, oral sepsis sets in, the one reacts on and aggravates the other until the vicious circle is completely established and alimentary toxemia with its numerous sequelæ is the result.

In Great Britain a few months ago a conference on education was held and one of the subjects debated was Diet as an Essential Factor in Education. A Mr. Hecht took a leading part in the discussion and avowed himself an uncompromising opponent of the stodgy soft monotonous diet of the age, but confessed that he could not conceive how children at school could be taught to see the error of their ways while their teachers set them so bad an example. Mr. Hecht averred that in Great Britain, at any rate, that as the teachers did not know how to feed themselves intelligently how could they be expected to feed children properly. According to Mr. Hecht the teacher, when a student, is fed upon a stodgy monotonous diet, eats the stuff too fast, and in his greed is prone to "afternoon tea and midmorning snacks," thus offering to students of dietetics spectacles of tragedy.

To the perhaps jaundiced eye of Mr. Hecht more pernicious by far than the untimely snack or cup of tea is the milk pudding which he regards as the bane of the race, the serpent in our paradise. However, although the British teacher quoted above is inclined to employ the language of hyperbole in descanting on the diet of the school boy or girl, of the embryo teacher, or of the full fledged teacher, his views, on the whole, are right or strongly tinged by common sense. There is no doubt that a great deal too much soft food, highly milled bread, the outer covering of the grain should always be left in the flour, too much liquid drunk with meals, including iced water and black coffee, and too much candy eaten in this country by persons other than teachers, but who lead a life as sedentary and more self indul-

gent. The salvation of the American as regards his diet compared with the Briton, and which counterbalances largely the greater amount of exercise taken by the average business and professional man in Great Britain, is his greater consumption of uncooked ripe fruit, which helps to make up for the lack of vitamines in his other articles of diet.

Cooking in civilized countries is often a drawback to good health. As a rule, food is cooked too long and some of the nutritive or health giving properties are depreciated or destroyed, vitamines for instance. Several vegetables as the salad vegetables should be made whenever possible a customary part of the diet. However, as Kipling might say, that is another story. No excuse is required for dwelling on the question of diet at such length, for unsuitable food and eating too much of it are responsible for causing or exciting into activity in those predisposed a very long list of diseases or conditions of invalidism. In the prevention of disease diet is a dominating if not the predominating factor. The modern diet table and modern methods of preparing food require revision and although "Peril of Pudding" may seem an absurd title for a medical editorial if but taken for what it is intended to be as a synonym for the soft vitamine lacking foods so widely used nowadays, it is quite timely and to the point.

THE EFFECT OF METHYL GUANIDINE ON BLOOD PRESSURE

The rise of blood pressure has been attributed to several causes. Many authorities now believe that not only hypertension but some other forms of faulty circulation or of heart disease are due to toxic influences initiated or promoted or initiated and promoted by metabolic disturbances. Further, it is held by some that these metabolic disturbances are owing to gastrointestinal troubles which eventually reach the stage of chronic intestinal stasis and a poisoning of the system.

In *Johns Hopkins Hospital Bulletin,* May last, is an article by Ralph H. Major and Walter Stephenson of the University of Kansas School of Medicine recording some experimental investigations made by them as to the effects upon the blood pressure of methyl guanidine. The investigators point out it is evident that any product of metabolism able to produce a striking rise in the blood pressure, could, if not excreted properly, induce very marked changes. It has been suggested that such a substance may be responsible for the high blood pressure observed in essential hypertension, in chronic nephritis, and in allied conditions such as eclampsia.

Rutscher and Lohmann first described the presence of methyl guanidine in the urine of normal individuals. Achelis described its presence in the urine of the dog, horse and man, pointing out that, although the horse eats no creatinine, he excretes considerable quantities of methyl guanidine. Roch noted the presence of guanidine compounds in the urine of dogs which had been subjected to parathyroidectomy. Noel Paton and Findlay described an increased urinary output of guanidine compounds in tetania parathyreopriva and idiopathic tetany, and Findlay and Sharpe and Mattrass and Sharpe found an increased excretion of dimethyl guanidine in idiopathic tetany. Sinalnicoff and Boxshik in a brief summary describe a present effect of dimethyl guanidine. Their results resemble closely those obtained by Major and Stephenson.

The experiments on dogs by Major and Stephenson showed not only the prompt rise of blood pressure but its persistence. Another point was that section of both vagi produced no increase in the heart rate and no change in the blood pressure as noted previously by Sinalnicoff and Boxshik, which fact points to a powerful vasoconstrictor effect of methyl guanidine as the most probable cause of the marked hypertension. Several records of the effect of methyl guanidine upon the blood pressure in man were obtained. The substance was injected intravenously in doses varying from .045 gm. to 0.8 gm. per kilo. No unpleasant symptoms, aside from a sense of slight fullness in the head and a slight pounding of the heart, were noted. The systolic and diastolic blood pressures were promptly elevated and these elevations persisted for one hour. The investigators think as a result of their experiments and those of others that methyl guanidine if produced in excess in the body, or if not excreted by the kidneys, might cause a rise of blood pressure.

As stated, if poisonous substances of putrefaction are found in the intestines to excess, possibly by long continued constipation, the entire system may be likely to be affected by these toxins, and high blood pressure may be one of the results. If this be so, such a condition may be prevented from occurring by suitable diet and by healthy habits of life generally and especially by paying proper attention to the functions of excretion and elimination. Also the condition when developed may be remedied or greatly relieved by taking the necessary steps to encourage and maintain satisfactory elimination and excretion.

The probable presence of substances in the urine capable of exercising a profound influence on the blood pressure has been and is being discussed by numerous investigators. The results of the experiments at the University of Kansas tend to show that methyl guanidine in the urine in excess if not excreted by the kidneys may be a cause of high blood pressure. It seems possible that such excess may

be brought about by the prolonged retention in the intestines of waste food products with resulting toxemia, and the treatment indicated would appear to be that stimulation and excretion are promoted and as far as the urine is concerned it should be disinfected as far as is possible.

A REMARKABLE WOMAN SURGEON

The first woman to take the M.D. of London University has just published her reminiscences at the age of seventy-eight. Dr. Scharlieb was born in London in 1845 and in 1865 married Mr. Scharlieb, an English barrister, practising in Calcutta and went out to India. Impressed and distressed by the sufferings of a large section of Indian women during childbirth, the caste prohibitions prevent them from having the services of male doctors, she studied midwifery in the Anglo-Indian hospitals.

Eventually she prevailed upon the authorities to permit her to study medicine and in 1877 secured a license to practise from the Madras Medical College. Dr. Scharlieb returned to London in 1878 at the time when the women's fight for medical privileges was at an acute stage. The famous Mrs. Garrett Anderson had started the campaign in 1860 and was joined eight years later by Mrs. Jex Blake. These women, the advance guard of the suffragettes, based their claims on sex equality, which in the mid-Victorian days when women to seek publicity was thought positively indecent, was highly unpopular.

However, after a vigorous battle lasting for more than sixteen years, an Act of Parliament was passed enabling women to obtain degrees in medicine and qualifications in surgery. In 1874 Mrs. Garrett Anderson founded the School of Medicine for Women in Bloomsbury, London, which remains the only one in England restricted to women, and in 1877 the Royal Free Hospital nearby opened its doors to women students in training at that college. At the present time Dr. Scharlieb is president of the college. It was not, however, until 1908 that the Royal Colleges of Physicians and Surgeons agreed to grant their diplomas, and it is only quite recently that the former college has opened its fellowship to women.

In India, Dr. Scharlieb was the pioneer in reforming conditions in such a way that the native women were enabled to have the services of doctors of their own sex. In 1887, owing to ill health, she left India never to return and has since practised in London as a leading consultant in diseases of women.

Dr. Scharlieb's *Reminiscences* are of great historical interest and, in addition, is an intriguing human document. Although in America and Great Britain the movement to make legal the status of the woman doctor and to remove the disabilities which formerly hampered her scope of activity is comparatively new, in some other countries there have been women medical practitioners for ages.

The best description of the history of women in medicine is given by Mme. Melanie Lipinska, *Histoire des Femmes Médicins*. As a matter of fact Dame Trot, so well known to children, is a corruption or abbreviation of the name Trotula, the illustrious authoress of several noted books dealing with female ailments who flourished as far back as in the eleventh century at the most famous medical school of medieval times, that of Salerno in Italy. It is said that extracts from her works and descriptions of her operations show that she was a capable obstetrician and gynecologist. Women in medicine from the point of view of history should provide a fascinating study.

As regards the future of women in medicine, in spite of the fact that Dr. Scharlieb was a pioneer, indeed something of a revolutionist, she is imbued with mid-Victorian ideas and believes that woman's sphere in medicine or surgery should be comparatively circumscribed. She insists that the true *raison d'être* of medical women is to deal with midwifery and the diseases of women and children. She practised what she preached. However, Dr. Scharlieb is extremely optimistic as to the future prospects of women in medicine and surgery, that is, within the limits of what she deems is their particular province, holding that there is ample room for their services both in private practice and in public health work in Great Britain and especially in India. She points out that in women as in men character and personality are of equal importance with medical knowledge. Book work, and she might have added laboratory work, and ability to pass examinations are not sufficient in the makeup of the capable practitioner. The treatment of the sick demands other qualifications.

HOME HOSPITAL CARE FOR CONSUMPTIVES

A ten year demonstration of the home hospital plan for the treatment of tuberculosis has been conducted in New York City by the Association for Improving the Condition of the Poor. Recently the association has issued a report on this work. The tests were carried out at the home hospital at 315 East 158th Street. Here, when a parent was stricken with tuberculosis, the entirely family was put under medical supervision. This plan is considered not only more effective and more humane than most other methods of caring for the tuberculous, but is also equally economical to the community. When tuberculosis appears in a family, the usual routine places the father or mother in a sanitarium, and the

children in a preventorium, in a foster home, or with friends or relatives of the family. The patient is likely to worry separated from his or her family, and progress is retarded; or he hastens to leave the sanitarium before recovery is complete. "The home hospital," says the report, "is a demonstration of the results which can be secured by housing the tuberculous patient and his family in a wholesome environment, by supplying the family with sufficient relief to provide for an adequate standard of living, and by providing the necessary medical and nursing care, not only to insure the recovery of the patient, but to prevent tuberculosis from occurring among those members of the family who previously had not been afflicted."

When the home hospital idea was first promulgated, the objection was made by some that without complete segregation many new cases of tuberculosis would develop in the institution itself. Within the ten years' life of the home hospital, not a single case has developed while a family was in the institution. This is attributed to the education in health matters given by the hospital to all within its walls.

That the effects of the treatment are lasting is shown by the fact that practically sixty per cent. of the patients, in spite of their tremendous handicap, are able to assume full responsibility toward their families after discharge. Of those discharged as quiescent, practically eighty per cent. were found on the followup to be alive and productive.

ILLUMINATION AND THE HUMAN EYE

Conditions of illumination in our streets, public conveyances, homes, offices, factories, and public buildings are year by year becoming more important as problems for the physician, the hygienist, and the engineer. Charles Sheard, Ph.D., chief of the physics section of the Mayo Clinic, writes an interesting article in a recent issue of the *Nation's Health* on the values of light as they influence visual acuity and the demands made upon the visual organs. The chief rules given are the following: The first fundamental principle of good lighting is that the light shine on the object under gaze, not in the eyes of the observer; the best remedy is the use of diffusing glass globes, reflectors, or shades. The contrast of brightness should be kept within a ratio of one to one hundred; this means the adoption of indirect lighting or semiindirect lighting in which the brightness of the bowls is reduced. Localized lighting should be used only in conjunction with some good general system of lighting so as to avoid too marked contrasts.

An important point in illumination where close visual work is to be performed is to so arrange matters that the glare of reflection from polished surfaces is avoided. The eye works with approximate normal efficiency upon surfaces possessing an effective luminosity of about one lumen per square foot. Excessive illumination, as well as inadequate illumination, strains and fatigues the eye in the endeavor to secure sharp definition. Intrinsic brilliancy of more than five candle power per square inch should be reduced by a diffusing medium if the rays enter the eye at an angle below 60° with the horizontal plane.

Flickering, unsteady, or streaky illumination strains the eye in its endeavor to maintain vision. Ultraviolet radiation percentagely in excess of that present in daylight as well as infrared radiation from high temperature molten surfaces are to be avoided for hygienic reasons through the use of special protective glasses.

The psychological laws of association and suggestion should be regarded, since, if there is total absence of visible light sources and of shadows, there may be complaints. In natural lighting through windows, the windows ordinarily should be as large a percentage of the total wall area as possible. Window shades indiscriminately used are conducive to contrast and glare effects; translucent screens or shades are usually far better. Ground glass and such materials should be avoided in window sashes below the level of the eye as they cause an increase of brightness in the retinal images thrown on a portion of the retina unaccustomed to such brightness. Dark colored finishes, and dark walls and ceilings should be avoided if ocular comfort is desired, since glaring contrasts are likely to be introduced.

Illumination conditions are important factors in conserving vision and enabling the eye to function comfortably. If illumination conditions are good, and yet the eyes become fatigued and ache, then the remedy may be in the hands of those who make it their work to alleviate the refractive errors of the eye.

ALCOHOLIC MENTAL DISEASE

In an article on Prohibition and Alcoholic Mental Disease, by Horatio M. Pollock, Ph.D., statistician of the New York State Hospital Commission, and Edith M. Furbush, statistician of the National Committee for Mental Hygiene, the following conclusions are stated as justified by the data presented in the article. This article appeared in the *American Review* and was reprinted in the April issue of *Mental Hygiene*.

Alcoholic insanity in this country is now much less prevalent than it was in 1910, but more prevalent than in 1920. The rate of decline since 1910 has been greater among women than among men. The reduction in alcoholic cases is due in part to a change in the habits of the people and in part to restrictive laws.

The rate of alcoholic insanity is much higher among the foreign born than among the native white population, and is extremely low among native women of native parentage. The rate is higher among negroes than among native whites. The enforcement of prohibitory laws is largely a matter of changing the more or less fixed habits of our foreign born population.

The rate of alcoholic insanity is much higher in cities than in rural districts. There is practically no alcoholic insanity among women in rural districts. Alcoholic insanity occurs principally in advanced middle life, following several years of excessive drinking. With respect to education, economic condition, and marriage, patients with alcoholic insanity do not differ greatly from the general average adult population.

LUNCHEON TO OVERSEAS MEDICAL REPRESENTATIVES

Many medical men representing the United States and the British Dominions overseas have visited Great Britain in connection with the British Empire Exhibition. In order to take part in welcoming these distinguished medical visitors the *Lancet* on July 17th gave a luncheon in their honor at the Hotel Victoria, London. Sir Ernest Hodder-Williams, C.V.O., the chairman of the *Lancet,* presided, and welcomed the guests in a witty speech. He referred to the fact that although physicians had dosed him frequently with nauseous concoctions he was not going to get his own back on the doctors by making a long speech to them. He pointed out that the *Lancet* had celebrated recently its hundredth anniversary, and that during the time it had been in existence nothing was more remarkable than the way in which there had come into being a real unity of work and purpose in medicine among the English speaking peoples, a constant interchange of views and works to the immense benefit of medicine and mankind. British medicine recognized no sundering seas and in the paper which he represented more and more space would be devoted in the years to come to the record of the doings and attainments of overseas visitors.

Sir Squire Sprigge, the editor, also welcomed the guests and voiced his regret that had it not been that many of the medical men who had made the trip from overseas had been compelled by the call of duty to return, the gathering would have been even larger. As it was, the quality of the response was significant. He drew attention to the immense progress that had been made in journalism including medical journalism, since the establishment of the *Lancet.* The increased facilities of intercommunication had revolutionized foreign correspondence, and as an example of this he referred to the foreign correspondence of the *Lancet* one hundred years ago as compared to the present time. This was only possible because of the extraordinary goodwill of the people at the peripheral centres toward the people at the old centres.

Obituary.

ANDREW ROSE ROBINSON, M.D.

Dr. Andrew Rose Robinson, of New York, died on July 8, 1924, at his country home at Caledon, Ontario, Canada, and was buried at Boston Mills, near Toronto. Dr. Robinson was born in Claude, Canada, on July 31, 1845. He was graduated in medicine from Bellevue Hospital Medical College in 1868; he received the degree of M.B. at the University of Toronto in 1869, the degree of L.R.C.P. at the Royal College of Physicians of Edinburgh in 1870, and L.R.C.S. at the Royal College of Surgeons, Edinburgh, in 1870. He studied in London, Paris, and vienna, and received many degrees and honors.

ANDREW R. ROBINSON, M. D.

Dr. Robinson was a member of the New York Academy of Medicine, and of many local and national organizations. He was one of the founders of the Polyclinic Hospital, serving as vice-president, and also as treasurer, for many years, and in his late years acting as professor emeritus; he was also an early supporter of the New York Skin and Cancer Hospital, and later served as consulting professor; he was connected with the Memorial Hospital for ten years. He was foreign corresponding member of the Société Francaise de Dermatologie et de Syphilographie; president of the section for dermatology and syphilography of the Ninth Medical Congress, 1887; and also addressed the International Congress of Dermatology at its meeting in Berlin.

His writings were in French, English, and German, mainly on the subjects of dermatology and cancer. He wrote the prize essay for the Bellevue Medical College Alumni in 1877, on Sycosis, receiving the only money prize ever given by the institution. His greatest achievement was a *Manual of Dermatology,* published in 1884. At the time of his death, he was preparing another book. He worked untiringly on microscopic and pathological investigations.

Dr. Robinson's manner was simple and unassuming, and his patients looked upon him as friend as well as physician.

News Items.

Anthrax.—It has been estimated that twenty thousand head of livestock have been lost owing to the recent epidemic of anthrax in Louisiana, the worst outbreak since 1901.

Memorial Tablet.—A tablet is to be placed on the lawn of the city hospital of Fayetteville, Ark., by the Arkansas Medical Society, as a memorial to Dr. Welch, its first president.

Memorial Ward.—A maternity and children's ward at St. Joseph's Hospital, Far Rockaway, New York, is planned in memory of the late Dr. William L. Mulcahy, and funds are being raised.

New Scholarship.—An anonymous donor has given the University of Virginia Department of Medicine $15,000 to establish a scholarship in memory of Dr. Richard H. Whitehead, a former dean.

Rural Health.—The legislature of Massachusetts has authorized a study of the adequacy of medical service in rural districts. Dr. George H. Bigelow, of Boston, is chairman of the committee.

Iodine in Drinking Water.—A decision on the question of treating the water supply of Minneapolis with iodine, which has been under consideration for some time, has been postponed to permit further study.

Women Physicians in Japan.—The *Japan Medical World* reports that there are about twelve hundred women physicians in Japan, and that the Tokyo Medical College for Girls admits about one hundred and thirty students

New Convalescent Home.—A home for boys from ten to sixteen years of age, recovering from major operations and serious illnesses, is to be built at Valhalla, New York, in the Westchester Hills, by the Children's Aid Society. Funds for the land and the buildings are the gift of Mr. Dunlevy Milbank. There will be accommodations for about five hundred boys.

New Society Organized.—The Tuberculosis and Public Health Association of Louisiana has been formed, with Dr. William H. Seeman, of New Orleans, president; Dr. Hector E. Bernadas, New Orleans, and Dr. Julius Dupont, Houma, vice-presidents; Miss Anna Kennedy, secretary, and W. R. Irby, treasurer.

Public Health Service.—Examination of candidates for entrance into the Regular Corps of the U. S. Public Health Service wil be held September 15th, at Washington, Chicago, San Francisco, and New Orleans. Oral, written, and clinical tests will be given. Information may be received from the Surgeon General of the Public Health Service.

Children's Clinic.—To carry out the provision of the law that children in institutions shall receive thorough mental and physical examinations, an institution known as the Children's Memorial Clinic has been opened in Richmond, Va., with Dr. Basil B. Jones as director. The clinic will furthermore act as a clearing house for the children's health problems of the community.

Industrial Hygiene Lecturers.—The Division of Industrial Hygiene of the State of New York maintains two lecturers in the field who are ready to give to manufacturing plants illustrated talks on industrial hygiene and accident prevention. Inquiries should be made to the Division of Industrial Hygiene, New York State Department of Labor, 124 East 28th Street, New York.

Judges for Essay Contest.—Dr. Haven Emerson, Mr. Michael M. Davis, Jr., and Dr. Willard C. Rappleye have been selected as members of the committee for the awarding of the *Modern Hospital's* prize for an essay on "Interrelationships of Hospital and Community." Registration for the competition should be made to the Contest Editor, *Modern Hospital*, 22 East Ontario Street, Chicago, before September 15th.

Health Department Impostor.—A woman known as Mrs. Witt has been visiting farmers in the neighborhood of Davenport, Delaware County, New York, selling a book published by J. L. Cornish, who calls himself "Domestic Health Secretary." The book costs twenty dollars and promises to keep the purchaser "away from a doctor." Mrs. Witt poses as an agent of the State Department of Health. Anyone to whom she so represents herself is requested to telegraph the Department, collect.

Tuberculosis Conference.—The United States has been selected by the International Union Against Tuberculosis for its annual convention of 1926.

New Club Building.—The Medical Alliance, an organization of physicians, dentists, and pharmacists, has purchased a building on East Eighteenth Street, for a clubhouse.

Child Health Appointment.—Miss Emma Dolfinger has been appointed director of the health education division of the American Child Health Association, to succeed Miss Sally Lucas Jean.

Rush Medical College.—The old Rush Medical College of Chicago, built in 1875, is being wrecked in preparation for the building of the Rawson Laboratory of Medicine and Surgery, part of the new program of the University of Chicago.

Civil Service Examinations.—An examination for the position of technical assistant in sanitary bacteriology in the Public Health Service will be held on October 8th. The entrance salary will be $1,860, with advance without change in assignment up to $2,400. Application may be made to the U. S. Civil Service Commission, or to local examiners.

Coming Meetings of Societies.—The annual meeting of the Indiana State Medical Association will be held in Indianapolis, September 24th to 26th.

The New England Surgical Society will hold its annual meeting at Hartford, Conn., September 26th to 27th.

The American Chemical Society will meet at Cornell University, Ithaca, September 8th to 13th.

Reporting Cases of Puerperal Septicemia.—The Division of Maternity, Infancy and Child Hygiene, New York State Department of Health, is asking the cooperation of physicians in reporting cases of puerperal sepsis as well as deaths. Such reports are authorized under the Sanitary Code, but that there has been laxness is shown in the fact that in the period from 1920 to 1923, 1,148 deaths were reported but only 877 cases.

Foreign Visitors Study Health Work.—Dr. Vincent G. Babecki, of Warsaw, Poland, and Dr. C. F. Challappah, of Colombo, Ceylon, are in the United States studying health administration as guests of the International Health Board.

New Chair at Jefferson Medical College.—A new chair has been created at the Jefferson Medical College, to be known as the Department of Bronchoscopy and Esophagoscopy. Dr. Chevalier Jackson has been elected to the professorship, and Dr. Fielding O. Lewis has been elected to fill the chair of laryngology vacated by Dr. Jackson.

Personals.—Dr. John Bland Sutton, president of the Royal College of Surgeons, was a visitor in New York recently.

Dr. Leopold Jache, of New York, is chairman of the American Committee of Arrangements, in the plans for meeting of röntgenologists in different cities of England and Scotland, in July, 1925.

Dr. Harley A. Haynes has been appointed director of the University Hospital of Ann Arbor, succeeding Dr. Christopher G. Parnall.

Dr. Carl Arthur Hedblom, of the Mayo Clinic, has been appointed professor of surgery at the University of Wisconsin Medical School.

Dr. Robert C. Courtney, of Richmond, Va., has been appointed a member of the Governor's Advisory Board for Mental Hygiene.

Dr. Henry Hall Forbes, professor of laryngology at the Post-Graduate Medical School, New York, has been studying at the University of Bordeaux for three weeks.

Dr. Joseph Franklin Montague lectured before the proctological section of the Royal Society of Medicine on the subject of Pruritus Ani.

Dr. Smith Ely Jelliffe, as an official delegate from the American Neurological Association and the American Psychiatric Society, has returned from Europe after attending a meeting of the Alienists and Neurologists of France and the French Speaking Countries, held in Brussels the first week in August.

Dr. Leopold S. Vaccaro, of Philadelphia, has been honored by the King of Italy, by being made official chevalier of the crown. Dr. Vaccaro is director of the Italian Child Clinic, an instructor at the University of Pennsylvania school of medicine, and is on various hospital staffs.

The Allgemeine Krankenhaus

GUSTAV BAAR, M.D.
Vienna

Three hundred years ago the grounds enclosed by the Alserstrasse and Spitalgasse were occupied by a large county poor farm. In 1696 there were one thousand inmates, in 1724 over one thousand seven hundred. Empress Maria Theresia, in order to give some occupation to the inmates, introduced the raising of silk in the institution. It is a matter of record that in 1768 there were thirty pounds of pure silk produced. By various bequests, like the one of Dr. Johann Frank (1686), Baron Thavonat (1725), new additions to the poorhouse were erected. To Emperor Josef belongs the credit of having transformed the poorhouse into a hospital and medical school, after the plans of his physician van Swieten (1754). The hospital contained two thousand beds *Saluti et Solatio aegrorum.* (The old inscription is still legible over the main entrance.)

The first medical clinic (founded 1754) was headed by Anton de Haen; he was succeeded by Stoll, Reinlein, Peter Frank, Peutl, Hildenbrand, Raimann, Hildenbrand, Lippich, Skoda, Duchek, Nothnagel, Noorden. The second medical clinic (founded 1849) was held by Oppolzer, Bamberger, Kahler, Neusser. The third medical clinic (founded 1892) was held by Schrötter.

The first surgical clinic was held by Steidele, Kern, Wattmann, Dumreicher, Albert, Eiselsberg. The second surgical clinic (erected 1841) was held by Schuh, Billroth, Gussenbauer, Hochenegg.

The eye clinic was held by Beer, Rosas, Arlt, Stellwag, Schnabel; the second eye clinic (founded 1873) by Stellwag, Jäger, Fuchs.

Obstetrics came to prominence under Boer (1789), Klein, Braun, Schauta. A second obstetrical and gynecological clinic was inaugurated in 1874 by Spaeth, followed by Breisky, Chrobak, Rosthorn.

The height of medical fame was reached about 1840, when Skoda taught chest diseases (percussion and auscultation!) and Rokitansky occupied the chair for pathological anatomy in his newly built institution, adjoining the old hospital. It was then that physicians from all parts of the world migrated to Vienna, to finish their education. Vienna had become the Mecca of physicians. The principle of speculation was abandoned in favor of that of observation. In quick succession the new specialties arose: Hebra taught skin diseases, Sigmund syphilis. The chair for laryngology was founded 1869, for psychiatry in 1870, for otiatry in 1872; another psychiatry clinic was founded 1878 and a clinic for nervous diseases in 1899.

There were two thousand beds at the disposal of the teaching clinicians. According to the stipulation made by Emperor Josef, two thousand beds had to be maintained for sick people, prevented the use of space for other purposes, required by the evolution of modern medicine: laboratories, kitchens, nurses' and physicians' rooms, larger lecture rooms, etc. The maternity home located within the *Allgemeine Krankenhaus,* with eleven thousand confinements a year, took up too large a space—and there was no other maternity home to be had in Vienna. Nurses and many of the house physicians could not be housed within the hospital. This facilitated the spread of contagious diseases, and made isolation impossible. There was a time, when mortality from puerperal fever reached thirty-three per cent.—it was the same time that Dr. Semmelweiss tried to emphasize the importance of contamination in the etiology of puerperal fever, but met only with shortsightedness and prejudice on the part of his colleagues. Thus Vienna missed its chance of discovering the principles of antisepsis.

FIG. 1.—I to XIII are the thirteen courts, of which I to IX are in use now, while X is the old military pathological institute (Josephinum); XIII the former Garrison Hospital.
(1)—(55) are staircases.
1—90 are wardrooms.
□ are 32 lecture rooms.

Men, like Billroth, realized, that the time when Hebra, Skoda, Rokitansky, and Oppolzer were able to make their epochal discoveries in modest shacks, had gone by, that modern research required modern institutions, and opened their fight for an up to date hospital in 1889; Billroth's colleagues signed an appeal to the government, threatening to give up their positions. This had the desired effect and in 1908 there arose five new, up to date clinics, on the grounds of the former insane asylum, near the rear entrance of the old *Allgemeine Krankenhaus.*

While the building plan provided for eighteen clinics—it is

FIG. 2.—Allgemeine Krankenhaus.

more than doubtful, if the rest of the planned thirteen clinics will ever be built, considering the upset financial conditions and the reduced size of the present republic of Austria.

The two clinics for women (Schauta and Chrobak), including the isolation pavilion in which both share, cover thirteen per cent. of the area of fifty-one thousand meters allotted to them, to wit 3,235 square meters for each clinic and five hundred and twenty square meters for the isolation pavilion, while eighty-seven per cent. of the area—to wit forty-four thousand square metres—is given to garden plotting. Each of these clinics comprises a main structure with three wings, four floors. They are up to date in every particular: the transition from floors to the walls and the walls to the ceilings is rounded, all walls show oil and enamel finish. There are no thresholds at the doors to avoid shaking the patients while being transported in their roller beds. There are separate rooms for sterilization, narcosis, wakening from narcosis, labor wards, tea kitchens, laboratories, hot and cold water in every room, baby tubs for the newborn, plenty of telegraphs and telephones, uniform electric clock devices in all rooms, electric light system; a most modern ventilation plant pumps fresh air from the garden into every room; steam heat. Special space is given for photographic and Röntgen work; an institute for experimental pathology with special operating rooms. The wards have twenty-three to twenty-four beds; there are also smaller rooms having one to three beds for restless, infectious or malodorous cases. The rooms destined for dispensary patients, admission, lectures, students' dormitories are located near the main entrances—thus separating the sick from all possible noises. The pregnant women occupy the basement, to save them stair climbing and facilitating the shortest possible exit into the gardens. Each clinic has 232 beds for obstetrical, fifty-eight beds for gynecological cases and twelve to eighteen beds in the isolation pavilion. There are also socalled exchange rooms, meaning rooms, which after having been disinfected, remain empty for a few days and are aired in that time. As stated, only five clinics obtained such splendid new quarters: two obstetrical-gynecological (Peham and Kermauner), one for children, (Pirquet), one for internal medicine (Wenckebach), one laryngology and otiatry (Hajek and Neumann)—the other clinics were doomed to remain within the walls of the old *Allgemeine Krankenhaus* and are striving hard to make the best of their crowded condition.

The *Allgemeine Krankenhaus,* with its damp old walls constitute one of the most hideous looking landmarks in beautiful Vienna; it resembles an old stable of a mediaeval country seat rather than an hospital for the sick.

Professor Hochenegg has endeavored for years to convince the authorities of the impossible conditions prevailing in the surgical clinics of the old *Allgemeine Krankenhaus*: to illustrate this claim we may mention, that the number of students matriculated at his clinic was seven hundred, while the seating capacity of his lecture room was only two hundred and fifty.

His latest plan, for the support of which he tries to enlist the influence of the Vienna Medical Society, is to move the patients not used for clinical purposes into the neighboring garrison hospital and hospital for army officers—evacuated since the dismemberment of the old monarchy and the dissolution of the large standing army. As the government,

in pursuance of its saving policy, has already reduced three medical department of the *Allgemeine krankenhaus,* the latter would become spacious enough to allow of temporary improvements; it could be transformed from a formerly mixed hospital into an institution for clinical teaching only.

As everybody realizes that the rapid fall of Vienna's once great medical reputation is due to a large extent to the lack of equipment and facilities for modern research work, Hochenegg's efforts in behalf of the clinics seem to meet a better fate than his calls for other reforms among the medical profession.

Foreign Correspondence.

LONDON LETTER

(From our own correspondent)

LONDON, *June 22, 1924.*

EMPIRE FIGHT AGAINST CANCER

The second quarterly meeting of the Grand Council of the British Empire Cancer Campaign was held on April 15th. Material advances were announced in the activities of the work of the campaign. The Scientific Advisory Committee, which was set up by the Royal Society and the Medical Research Council in consultation with the British Empire Cancer Campaign a few weeks ago, has already held two meetings, and it has decided to meet every month until further notice. The members of the committee have long been in communication with scientists in all parts of the world where cancer research is being carried out, and thus the committee will be in a position to obtain data to assist those carrying out cancer research, to prevent overlapping of effort and to keep the public generally informed of the activities in cancer research in other countries. A letter was read from the Ministry of Health asking that steps might be taken to help close and continuous cooperation between the Ministry of Health Committee dealing with cancer, and the British Empire Cancer Campaign, and on the suggestion of the Ministry of Health, Professor Gowland Hopkins, Cambridge University, and Professor Lazarus Barlow, professor of experimental pathology, Middlesex Hospital, were appointed liaison officers between the two bodies.

CAMPAIGN FOR THE INFANTS' HOSPITAL

Of all the campaigns being waged in this country for the voluntary hospitals, and some of them are of the most vigorous nature, none is more vigorous than that for the Infants' Hospital, Vincent Square, London. The increased willingness to give to the hospitals is due, perhaps, to the desire of the public generally to retain them as voluntary institutions and not allow them to come under the bureaucratic régime of nationalization. There is a party in this country which believes or at any rate preaches the doctrine that nationalization is a panacea for all evils. They are blind to the history of nationalization in other countries and fail to understand that competition is the breath of progress. However, the people of this country are on the whole warmly attached to their voluntary hospitals and are opening their pocketbooks in a remarkable way to keep them well above water. The campaign for the Infants' Hospital is extremely strenuous. It has been taken in hand by the brothers Berry, among the largest newspaper proprietors of the country.

BACILLUS OF FOOT AND MOUTH DISEASE

Dr. Frosch, professor at the College for Veterinary Surgeons at the University of Berlin, informed the world recently that he and his assistant, Professor Dahmen, have discovered the bacillus which is the cause of foot and mouth disease. A full account for scientific readers in the *Berlin University Veterinary Journal* will have appeared by the time this letter is published. It may also be said that the experiments have not been tried out at Koch's Institution and the Board of Health of Berlin. The bacillus, or virus, is extremely minute filterable, of the kind that Flexner isolated in poliomyelitis. It is so small, indeed, that it cannot be seen by means of the most powerful microscope and the German investigators made use of photography for the purpose. They employed a photographic apparatus which magnifies on the sensitive plate the microscopic view of the bacteria to more than double the size seen through the microscopic lens. They are also stated to have worked at night in complete darkness with perfect quiet in the building to prevent the slightest motion of the camera. It is also stated that a culture has been prepared, so that not only have the bacilli been found but an easy method of propagating them. It seems, if this reported discovery is confirmed, that developments in the study of foot and mouth disease will proceed with great rapidity.

INSANITY AND CRIME

The text has just been issued of Lord Darling's bill to amend the law relating to the criminal responsibility of accused persons suffering from mental disease. The first clause provides that, 1. A person is not responsible to the law for an act or omission charged against him as a crime, if at the time of doing the act or of making the omission he is proved to be suffering from such a state of mental disease as deprives him: a, of capacity at the time to know, understand, and appreciate the physical nature and quality of the act done or omission made or b, of capacity to know, understand, and appreciate at the time that the act done or omission made was wrong; or c, if at the time the act was done or omission made he was suffering from such a state of mental disease as therefrom to be wholly incapable of resisting an impulse to do the act or make the omission. 2. A person who is suffering from mental disease at the time of doing the act or of making the omission charged against him as a crime and by reason of such mental disease is affected by delusions on some specific matter or matters, but whose mental condition does not render him irresponsible to the law within the meaning of sub-section 1 of this section is criminally responsible for such act done or omission made to the same extent and as if the facts with respect to which such delusions exist were real. The definition of insanity or of mental disorder is most difficult. Legal and medical authorities here are at variance as to this point and the general public is altogether a tsea.

NEW BOOKS

Three good books have been issued recently by William Heinemann (Medical Books), Ltd., London. *Insulin in General Practice,* by A. Clarke Begg, O.B.E., M.D., is a practical clinical guide to the use of insulin in the treatment of diabetes in general practice. This small inexpensive book gives all the salient facts on the subject couched in clear language and should be valuable as a reference book to general practitioners and students.

Organic Substances, Sera and Vaccines, by O. W. Barmalt Jones, M.D., F.R.C.P., is a description by the author of treatment in this sphere of therapeutics drawn almost wholly from personal experience. While there are some gaps, nearly everything is touched for by Dr. Jones.

A third book is a translation from the French by Dr. R. Scott Stevenson of *Ear, Nose and Throat Treatment in General Practice,* by that master of his subject, Dr. Georges Portmann.

Dr. W. Seaman Bainbridge's *Problem of Cancer* has been issued recently from the Barcelona Press, translated into Spanish by Dr. Rera, professor of clinical surgery at the Faculty of Medicine, Barcelona, with an appendix on the treatment of malignant neoplasms by radiation by Dr. Vicente, professor of radiotherapy at the Faculty of Medicine, Barcelona. It may be remembered that the second edition of Dr. Bainbridge's work on cancer was translated into French at the request of the King and Queen of the Belgians and was the first book printed and published at the Royal Press of Louvain University after the destruction of the buildings by the Germans.

INTERNATIONAL CLINIC OF PLASTIC SURGERY IN LONDON

During the war and after in England as in other countries, notably in France and in America, wonderful work was done in facial restoration. A large hospital for this branch of surgery at Sidcup, near London, was opened and in 1919 the writer had the privilege of witnessing there some of the results of plastic surgery and an operation for the restoration or betterment of certain facial deformities received in war performed by Major H. D. Gillies, C.B.G., the head of the Sidcup institution. It may be added that Major Gillies is well known in some of the large cities of America, as in 1920 he paid a visit to New York and a few other big centres, lecturing on his experience in the art of facial restoration. Moreover, Major Gillies published a year or so ago the best and fullest book on the subject. Recently, an international clinic for the practice of plastic surgery has been established in London. It is housed temporarily in St. Andrew's Hospital, Dollis Hill, a suburb of London, until funds are available to add a special wing to that institution for plastic surgery. Major Gillies is head of this department and his associate is Mr. T. Pomfret Kilner. There are also two American members of the staff, and one, Professor Lemaitre, representing France. The general purpose of the clinic is to preserve, improve and teach the knowledge of facial restoration and improvement, which was developed so greatly during the war. Surgeons of unquestionable standing only will be received as students, and dentists, artists, and sculptors will cooperate to make of plastic surgery a separate branch of surgical work. Lectures will be given and conferences held in different countries.

THE INFANTS' HOSPITAL, LONDON

The Infants' Hospital, Vincent's Square, is almost unique in its way. It is the largest infants' hospital in Great Britain, having fifty beds, several private wards, and the hospital buildings and equipment provided in 1907 and 1914 are well built, carefully chosen, and excellently adapted for their purpose. Also being situated in a poor neighborhood, its wards are always full and the outpatient department is large. The committee holding that the hospital's important work should be carried on in the most thorough manner possible, have added x ray and artificial sunlight installations, have improved the balconies for open air treatment and have the buildings and equipment put into a state of complete efficiency. This hospital is under new direction and may be strongly recommended to any American medical men coming to London for postgraduate work. The director, Dr. Eric Pritchard, has succeeded in getting the hospital into admirable working order. Lectures are given by him and the staff, round table conferences held, and as said before the clinical material is practically unlimited.

VIENNA LETTER

(From our own correspondent)

VIENNA, *June 1, 1924*

ARTIFICIAL MISCARRIAGE

The Society of Social Democratic Physicians has instituted a discussion regarding the Austrian penal law, which categorically prohibits the performing of artificial abortion. The discussion lasted two days. The socialist representatives of the medical profession wanted to tender a bill which permitted the artificial abortion during the first three months of gestation. The presidential chair was occupied by Professor Friedjung, who suggested that the question of artificial abortion be dealt with without prejudice, because the old law was not modern.

ANTITUBERCULOSIS SERUM

The Vienna medical clinics are making experiments with a new antituberculosis drug called aurocitin. This is the invention of Professor Holger Möllgaard, of the Agricultural High School of Copenhagen, Denmark. The drug is a chemotherapeutic preparation, and it was experimented with in the latter years extensively in the different states of Central Europe. Aurocitin is a gold salt which if injected into a tuberculous patient, produces toxines, which are likely to kill the tuberculous bacilli. Until now all experimenters have favorable experiences with this drug, which is manufactured now under the personal supervision of the inventor, Dr. Möllgaard. The Vienna experimenters have not published any reports on the results attained, but so much leaked out already from the clinics, that the drug is worth the trial although it is still far from being called a remedy against tuberculosis. It controls the fever, stops coughing and increases the appetite. Professor Möllgaard was formerly assistant in the physiological laboratory of Copenhagen.

THE ZUCKERKANDL MEMORIAL

Under the arcades of the Vienna University the memorial of the late famous anatomist of the Vienna University, Emil Zuckerkandl, was solemnly unveiled recently. The memorial is a lifesize statue made by a famous sculptor, Anton Hanaks. The bronze statue stands on a marble pedestal, and illustrates the great anatomist in a working coat, depicting him when pointing with his right, bent arm, to the play of the muscles of the left hand. This motive of teaching anatomy strongly reminds one of the famous painting of Rembrandt, *The Anatomist.* The memorial is placed in the library corner of the arcade, in the neighborhood of William Hartel, late Minister of Public Education of Austria, and Professor Bamberger. The unveiling ceremony was attended by a huge crowd. It was touching, when a laurel wreath has been laid on the statue by the members of the *Danubia* society, wherein the late Zuckerkandl played a great rôle.

ALLEGED DISSECTION OF A LIVING MAN

The great council of the canton Geneva, Switzerland, has dealt repeatedly with the case of Professor Kummer, director of the surgical clinic at the university and the canton hospital. He was indicted by some employees of the clinic, and discharged from service, for having dissected a living man. The government council and the great council acquitted him after an investigation.

DEATH OF PROFESSOR PICK

Some days ago Professor Pick, teacher of psychiatry at the German University in Prague, died in the seventy-fifth year of life. Dr. Arnold Pick was a pathmaker in the domain of neurology. He resigned his post only two years ago. The death of Professor Pick, whose fame has spread well beyond the boundary of his fatherland, reminds one of the glorious period of the Prague school. There was no branch of psychiatry, where Pick did not work. His lectures were famous for their clarity. He was known as a man without a single enemy. His successor is Dr. Otto Plötzl, son of a well known Vienna writer.

PARIS LETTER

(From our own correspondent)

Paris, *July 4, 1924*

ALL SPECIALISTS NOW

In the days of long ago, that is to say in the last century, when it was still licit in the United States to go to port or sherry for a simile, Sir William Harcourt, the British politician, was likened in his last days to old crusted wine. And it was he, when dread of radicalism was expressed in his presence, who laughingly replied: "Socialists! Why bless you, we are all Socialists now!" It is no longer permissible, the Scriptures notwithstanding, to go to the vineyard for metaphors, but Sir William may still be paraphrased medically speaking, and the variant of his phrase fitting the present day is: "We are all specialists now." Take Professor Pinard, for instance. Professor Pinard is a delightful old man of more than eighty years, an authority on obstetrics and a member of the Chamber of Deputies in the bargain. His mission in life is to usher babes into this world, and so well has he accomplished this mission that he lays claim to having officiated at some twenty thousand accouchements. A simple arithmetical operation will show this to mean nearly ten a day since the age of twenty years, allowing for holidays, which is no mean record. But then Professor Pinard is of the old French school, noted for hard work!

Dr. Pinard is the selfconstituted apostle of puericulture in this country; it is alleged against him, indeed, that, like Mr. Dick, he cannot keep puericulture out of the memorial. No wonder then that the other day when, as the oldest member of the Chamber of Deputies, he was presiding officer at the opening sitting of the new Legislature, his inaugural speech was devoted in great part to childrearing, a very timely topic, as the declining birthrate is one of the most important of immediate problems in France. Some Deputies thought that the old professor was rather longwinded and went out into the lobbies to smoke. But what can you expect of a specialist if not to talk shop?

SPECIALIZATION GONE MAD

When a specialist thus talks shop and stops at that there is little harm done. The trouble is when he carries precept into practice. But after all everything is relative. L. Boudreau, of Bordeaux, has specialized in treating tuberculosis with tincture of iodine administered through the digestive channels. Like all apostles, he has faith abounding in this treatment. So do his patients, judging by the quantity of tincture of iodine which they ingurgitate. At all events, if the treatment does not cure tuberculosis, trustworthy witnesses assert that it does no harm, which deposition is gratifying when you consider that Dr. Boudreau, or more accurately his patients, have reached the astounding dose of three thousand drops of tincture of iodine a day. Needless to say, this quantity was reached progressively. The doctor and his trusting patients started with twenty to thirty drops a day some ten months ago. Rapidly the quantity rose to forty, to fifty, to sixty drops. The patients seemed to be making progress. The doctor's fellow practitioners shrugged their shoulders and declared that he must be mad. Perhaps he is, but that there is method in his madness is shown by the fact that from sixty drops the dose rose to one hundred and fifty, to two hundred, to three hundred; then by jumps to one thousand, fifteen hundred, two thousand, three thousand. Dr. Boudreau, of Bordeaux, has stopped at this quantity at present—a claret glass of tincture of iodine. The patients are none the worse apparently, perhaps they have improved, and the medical world is awaiting further reports of this highly specialized treatment.

ABLATION OF THE SPLEEN

Several French specialists are out after the spleen. Recently it was Professor Charles Richer, who declared that it is of mediocre use; now comes Professor Chauffard who will have none of it and who holds that it can be removed without inconvenience. Indeed, he is of opinion that in certain cases such removal is an advantage, for instance, in connection with icteroid maladies of congenital origin. In the *Journal de Médecine et de Chirurgie Pratique,* Pro-

fessor Chauffard reports the case of an icteric subject who had suffered for forty years and whose symptoms disappeared completely after the removal of his spleen. The theory is that the spleen is useless and that its normal functions may be well carried on by the liver. Consequently Professor Chauffard and other surgeons have this specialty—if your spleen bothers you, let us remove it for you.

THE BREASTS ALSO

Dr. Duclaux goes one better. His slogan is: if a woman complains that her breasts were painful, off they go. In a long communication to the Société de Médecine de Paris, he gives details of two cases of hypertrophy of the mammæ. In both instances the subjects were young women, of slight build and much devoted to sports. They complained of considerable hypertrophy, irksome and painful. The only rational treatment, in his opinion, was total amputation, with lateral incision.

WHAT'S IN A NAME?

In the opinion of Dr. Lévy-Darras, of Evian-les-Bains, the wellknown watering place in Savoy much frequented by Americans, specializing is a good deal in question of names. He implies that fashionable practitioners are tempted to find fashionable names for maladies which in themselves are far from new. For instance, nobody at the present time ever seems to speak of arteriosclerosis, whereas some time before the war no one spoke of anything else, so much so that engineers would say that the railroad systems of the country were suffering from arteriosclerosis! Dr. Lévy-Darras holds that the disease is as prevalent as before but that physicians have seen fit to change the name. Since the introduction into general practice of such sphygmometers as those of Pachon, Vaquez-Laubry and Lian, all the talk has been of arterial hypertension; the patient who has come fearing arteriosclerosis, hears that he is merely "hypertended" and goes away satisfied with the diagnosis. Speaking more seriously, hypertension is now looked upon as a sort of spontaneous equilibrium in the fight against kidneys stricken with sclerosis. It is generally accepted, moreover, that hypertension of the arteries is far from being always consecutive upon a lesion of the kidneys; that hypertension frequently precedes the renal lesion; and that there may even be hypertension without renal lesion. Brightism, consequently, has seen its importance increase in the matter of a symptomatology. Furthermore, it has become manifest that many minor symptoms of Brightism—this is the current phrase here since Dieulafoy studied the malady so successfully—are not peculiar thereto. In a word, too much importance has been conceded to chronic nephritis, and leading practitioners are of opinion that physicians should differentiate between the said chronic nephritis and a more general malady of which the renal lesion is only one complication. In fine, arteriosclerosis is reappearing in French medical terminology. What is it to be called now? Some propose Brightism. This is opposed on the ground that, because Dieulafoy saw fit to modify the definition handed down by Bright, there is no reason for modifying Dieulafoy's definition in its turn and making it mean more than renal sclerosis. Hence the search for a new name.

LATIN AMERICA LETTER

(From our own correspondent)

BALBOA HEIGHTS, C. Z., *July 21, 1924*

PUBLIC HEALTH LABORATORY IN COSTA RICA

Dr. Luis Schapiro, Senior State Director of the International Health Board, has just returned to the Isthmus and the Republic of Panama from an extended trip through Costa Rica. The purposes of the trip were twofold: A general inspection relative to the hookworm control campaign which is being intensively waged in that country; and supervision of the establishment of a public health laboratory at San José. This laboratory is being established through funds donated by the International Health Board in cooperation with the Government of Costa Rica. It will be under the control of the Department of Health of Costa Rica and will be directed by the Sub-Secretary of State. Costa Rica now has a well-rounded Health Department which is considered one of the best among the Central American countries. According to Dr. Schapiro, hookworm disease is rapidly on the decrease owing to the campaign which is being waged against it.

TYPHOID FEVER AT CARTAGO, COSTA RICA

There has been reported by cable to the Chief Health Officer of the Panama Canal an outbreak of typhoid fever in the city of Cartago, Costa Rica. A summer camp for the Boy Scouts of the Canal Zone had been established about three miles below this city and it was the intention of the scouts to make camp there during the months of August. On account of this epidemic this outing will not take place in Costa Rica. It is probable that the scouts will camp in the mountains of Panama in the Chiriqui Country.

THE CARIBBEAN YELLOW FEVER SURVEY

Dr. N. E. Connor, former Health Officer of the City of Panama, at present one of the directors of the International Health Board, was a recent visitor to the Health Department of the Panama Canal. Dr. Connor is en route to New York after having spent the past five months in a yellow fever survey of south Caribbean ports. He has visited and made intensive studies particularly in Trinidad, British, Dutch and French Guiana and Venezuela. He reports that the foci of infection of yellow fever have practically been destroyed in these places. There is a possibility, however, that there may be a focus of infection in Maracaibo. Dr. Connor says that Trinidad is in particularly good sanitary condition, a complete water and sewage system having been installed in the city. In the Guianas many suspicious cases of yellow fever have been reported but according to Dr. Connor these are, in his opinion, cases of a disease due to a spirochete producing a disease which simulates yellow fever. This undoubtedly has been introduced in these countries through the natives of Java, where the disease exists in endemic form.

MAJOR CONGER ARRIVES ON THE ISTHMUS

Major W. C. Conger, Medical Corps, United States Army, recently assigned to the Health Department of the Canal Zone, arrived on the transport *Chateau Thierry* July 20th. During the absence on leave of Dr. Henry Goldthwaite, Major Conger will act as Health Officer of Panama City.

Book Reviews

ANGINA PECTORIS

Die Angina Pectoris. Von Dr. med. Oskar Burwinkel. Halle a. S.: Carl Marhold, 1924. Pp. 30.

This is a short didactic presentation within the compass of thirty pages of the etiology, symptomatology and treatment of angina pectoris. As such it is quite satisfactory. The author adheres to the view that every case of angina pectoris is determined by some form of coronary artery disease with resulting myocardial ischemia. This theory does not explain every case. In the experience of the author syphilitic aortitis has become much more frequent since the introduction of salvarsan as a remedy for syphilis. This is an interesting point and deserves further study. Almost half of the pamphlet is devoted to therapy. There is no discussion of the surgical treatment of angina pectoris.

ELECTROCARDIOGRAPHY

Clinical Electrocardiography. By Sir Thomas Lewis, M.D., F.R.S., D.Sc., F.R.C.P., C.B.E. Third Edition. London: Shaw and Sons, Ltd., 1924. Pp. 126.

Sir Thomas Lewis's small monograph on *Clinical Electrocardiography* is so well known that it requires little additional comment. The chief change in this, the third edition, is a revision of the sections on auricular flutter and fibrillation to make them conform to the circus movement theory. Lewis now accepts the inversion of the T wave in Lead II as being, with few exceptions, a sign of grave prognostic import. Aside from the items just mentioned, there have been no changes of content, but considerable painstaking revision of phraseology has been made. It is most refreshing to read a book that is written with such care and precision. There are few authors who have so clear and succinct a style as that of Lewis, and still fewer who pay so much attention to accuracy in the use of words and the construction of sentences. The book should serve as a model of scientific exposition.

ELECTROCARDIOGRAM

Clinical Aspects of the Electrocardiogram. A Manual for Physicians and Students. By Harold E. B. Pardee, M.D. With fifty-six illustrations. New York: Paul F. Hoeber, Inc., 1924. Pp. 222.

Dr. Pardee has written a manual on the clinical aspects of electrocardiography which is accurate, concise, and well balanced. Controversial points are omitted, or barely touched upon, for the book is planned frankly as an elementary guide to students and practitioners. The author recognizes that the electrocardiogram is but one of many methods of examining the heart, and that it must be correlated with the complete history and physical examination of the patient. Following the first chapter in which the electrocardiogram is described and its physiological basis is discussed, the normal electrocardiogram is presented in some detail with due consideration of its normal variations. Subsequent chapters are devoted to an exposition of electrocardiographic changes due to hypertrophy of the auricles and ventricles, to myocardial abnormality, the clinical significance of abnormal waves, disturbances of rate or rhythm with a discussion of its clinical aspects. The final chapters are devoted to the theory of the electrocardiogram and to a description of the electrocardiograph and its operation. A well chosen bibliography concludes the volume. The book is well printed, bound and illustrated. The misspelling of the word "venous" on page 46, as well as a few other minor typographical errors, might have been avoided by more careful proof-reading. This manual should find a wide sphere of usefulness among students and practitioners as a text book of the elements of electrocardiography.

ARTERIAL HYPERTENSION

L'Hypertension Artérielle. Par Dr. Camille Lian et Dr. André Finot. Bibliotheque des Connaissances Médicales, Direger par le Docteur Appert. Paris: Ernst Flammarion, 1924. Pp. 247.

This book is one of a series of manuals on medical topics designed for the educated lay public, as well as for students and general practitioners. Its form, therefore, must of necessity be didactic. The presentation is clear and simple; not a mere compilation, but a critical summary based on the experience of authors. In the initial chapters there is a good sketch of the history of our knowledge of the circulation, as well as a lucid elementary delineation of the fundamentals of cardiovascular physiology. The technic and application of sphygmomanometry is discussed and the clinical phases of the hypertensive states are well presented. The authors have been successful in producing an interesting elementary and didactic manual on hypertension.

DISEASES OF THE CHEST

Diseases of the Chest and the Principles of Physical Diagnosis. By George W. Norris, M. D., and Henry R. M. Landis, M.D. With a chapter on the Electrocardiograph in Heart Disease, by Edward Krumbhaar, Ph.D., M.D. Third Edition, Revised. With 433 illustrations. Philadelphia and London: W. B. Saunders Company, 1924. Pp. 907.

The previous editions of Norris and Landis's textbook on *Diseases of the Chest* have established for it an assured place in its field. The new (third) edition, which has been carefully revised and much enlarged, should enlarge its circle of readers and its scope of usefulness. Many sections have been rewritten and new material on a wide variety of topics, such as shallow breathing, cyanosis, heart pain, arteriosclerosis of the pulmonary artery, rupture of the heart, tuberculosis of the heart, tumors of the heart, mycotic aneurysms, abortive and masked tuberculosis, and modes of death in pulmonary tuberculosis have been added.

It is unfortunate that the authors did not see fit to revise the section on myocarditis. They criticize the use of the term and then proceed to include under the category of chronic myocarditis a variety of conditions such as fibroid degeneration, fatty heart and brown atrophy. Not a few will dispute the statement that "the final stage in chronic valvular disease is, in the great majority of instances, muscular in-

sufficiency due to myocardial degeneration." As a matter of fact, the lack of correspondence between anatomical lesions of the myocardium, and the degree of muscular sufficiency has been established by a number of careful studies, such as those of Krehl and Aschoff.

In the section on intrathoracic tumors more emphasis might have been placed on their early recognition; on the importance of dullness and diminished breathing in older patients with cough. The use of the bronchoscope in their early diagnosis as well as the examination of pleural effusions for tumor cells should be discussed.

The book contains a wealth of information, well presented and richly illustrated. It is a work of value not alone to the medical student, but to every physician who is interested in diseases of the chest.

BIOLOGICAL THERAPY

A Practical Textbook of Infection, Immunity and Biological Therapy. By JOHN A. KOLMER, M.D. Third edition, 1923. Philadelphia and London: W. B. Saunders Company. Pp. 1210.

This book, which is already well known through its first and second editions to the medical profession, is invaluable to the practising physician because of the space devoted to therapy. It is of equal usefulness to the teacher for the concise expression of theory, careful attention to detail of technic, and the discussion of the relative value of various diagnostic procedures.

Of especial value to the practising physician is the chapter dealing with vaccines, sera, blood and nonspecific protein in the treatment of disease, and the not least important item is the accentuation of the difference between vaccines and serums, which is a point of significance to patients. The volume is comprehensive enough in scope for the scholar, clear enough in its diction and explanatory matter for the student, and about as useful to the medical profession as the Bible is to a Minister of the Gospel.

ANESTHESIA

Anesthesia. By James Tayloe Gwathmey, M.D. With Collaboration on Special Subjects. Illustrated. Second Revised Edition. New York: The Macmillan Company, 1924. Pp. 799.

Dr. Gwathmey published in 1914 the first edition of his monumental work on *Anesthesia,* which has remained the authority on the subject to the present time. The second edition retains much of the groundwork which distinguished the first edition and contains many additions which bring the work abreast with the knowledge of anesthesia gained during the world war and in the civil practice of the past ten years. The chapter on Colonic Anesthesia has been rewritten. That on Local Anesthesia by the eminent authority, Dr. James F. Mitchell, has been extended in accordance with the recent advances in this branch and its value increased by a large number of new illustrations. A new chapter on Synergistic Anesthesia with magnesium sulphate recounts the early work of Meltzer on this subject, a theoretical and physiological consideration of synergistic anesthesia and a practical account of the methods through which the author has achieved such remarkable results with this form of anesthesia. The chapter on Anesthesia During the World War will be read with the greatest interest. It results from Gwathmey's great opportunities and experience during the war and is written in his best style. Ethylene anesthesia is considered by Dr. Arno B. Lockhardt as a result of whose labors this anesthetic has risen from entire obscurity to a world wide interest in a period of a little over a year. The practical anesthetist will study with great advantage Dr. Arthur E. Guedel's chapter on Third Stage Anesthesia. It describes and elucidates Guedel's important discovery that "the eyeball with its varying positions and movements affords an anesthetic sign which, in proper classification and when considered in its association with other signs, is a reliable guide to the stage of anesthesia present." Following this reliable guide, it is possible to secure satisfactory anesthesia without entering the deeper stages which are danger zones for the patient. With the aid of these collaborators Dr. Gwathmey, in the second edition of *Anesthesia,* has produced a work indispensable alike to the student and to the specialist in anesthesia.

THE MALE GONADS

The Human Testis. Its Gross Anatomy, Histology, Physiology, Pathology, with Particular Reference to its Endocrinology. By Max Thorek, M.D. With 308 Illustrations. Philadelphia and London: J. B. Lippincott Company, 1924. Pp. 548.

This is one of the most complete books as well as the most satisfactory one that has appeared on the male gonads. The subject is attacked from many angles. Pathological states, alteration of function, and anomalies are each handled in a complete way. The various endocrine disorders are considered where the gonads are involved directly or indirectly. In the latter instance a broad point of view is taken, rather than the one where the gonads might be accused as the evil doers in every instance. Considerable attention is given to the work of Mott and Such, indeed almost the entire article which they published in the NEW YORK MEDICAL JOURNAL AND RECORD is quoted. As will be remembered by the readers of this JOURNAL, they discussed the relationship of dementia precox to the gonads. This book of Thorek's should have a wide appeal, being useful alike to the genitourinary specialist, endocrinologist, surgeon, clinician, and research worker. The illustrations are well chosen and excellently reproduced.

PHYSIOLOGY

Human Physiology. A Practical Course. By C. G. Douglas, C.M.G., M.C., D.M., F.R.S., and J. G. Priestley, M.C. D.M. Oxford: Clarendon Press, 1924. Pp. 232.

Here we find an outline of the practical course in human physiology given in the Final Honor School of Physiology in Oxford. In the main a study of the determination of function is stressed. This is done rather than any attempt being made to cover the entire field of physiology. The respiratory, vascular, renal, and alimentary systems are taken up in order and the various technical details given which are required to determine their respective states. For a textbook covering the field in this fashion, it is an admirable piece of work.

EVOLUTION

Evolution of Man. Essays. By G. Elliott Smith, M.A., M.D., Litt. D., D. Sc., F.R.C.P., F.R.S. New York: Oxford University Press, 1924. Pp. 159.

A series of light essays on man's evolution, easy to read and in the main valid. The only criticism that might be offered is that Smith falls into the common error that man studied himself with an equal degree to that of the study of his environment. He also considers man a beauty as compared to his progenitors. According to Smith man is a fine specimen, endowed with a thinking apparatus which he has used to a full measure. Many will agree with all this. However, we take issue with Smith and in all modesty postulate that so far as looks go, there is little to brag about. Man's ego has forced the concept and acceptance of all this. And so far as introspection goes, this has scarcely begun. Withal, Smith's book makes good reading.

MASTURBATION

Study of Masturbation and Its Reputed Sequelæ. By John F. W. Meagher, M.D., F.A.C.P. New York: William Wood and Company, 1924. Pp. 63.

This is a conservative treatise on masturbation, which covers the ground. In general Meagher takes a middle of the path attitude, varying between the extreme views held by Stekel, who finds in masturbation a harmless manifestation of physiosexual level, and more conservative workers, who see many evils in the train of this practice. Meagher has gone to many authorities and assembled their views clearly and compactly. The monograph gives a concise presentation of the subject and to many it will afford an entirely new point of view.

LAUGHTER AND COMEDY

Psychology of Laughter and Comedy. By J. Y. T. Greig, M.A. New York: Dodd, Mead and Company, 1923. Pp. 298.

An excellent piece of work, well built and studiously constructed. Full cognizance is given to the motives underlying this vital portion of our behavior. The attack is made from many well grounded angles. Surely we owe Greig a profound debt for this splendid book.

PHILIP GIBBS

The Middle of the Road. By Philip Gibbs. New York: George H. Doran Company, 1923.

Heirs Apparent. By Philip Gibbs. New York: George H. Doran Company, 1924.

Although Philip Gibbs' postwar novel, *The Middle of the Road,* has been frequently characterized by the literary critics as more of a study of social conditions in Europe after the war than a novel, the fact that it is also a most readable tale with interesting characters is testified to by a popularity that has earned for it the reputation of a "best seller on two continents." Perhaps the very fact that the characters in *The Middle of the Road* are rather more typical than individual has given it a broader appeal to the average reading public. At any rate, the tremendous social significance of the book, and its superb setting and background, justify it as one of the most important books of 1923. The descriptions and contrasts of postwar life and social conditions in England, France, Germany, and Russia, through which countries the "road" leads us, are drawn with the pen of the expert journalist and close observer of life.

Heirs Apparent is also more a social than a human document, but with the technic of characterization somewhat better developed. Yet the reader still feels that Gibbs is more of a reporter than a creator. He is the critical spectator rather than the interpreter of his personages, yet his criticism does not usually lack understanding. He is true to his philosophy of following the middle of the road.

Heirs Apparent is a study of postwar youth, born just too late for participation in the war, but deeply affected by its aftermath. These young people are self-conscious, critical of themselves, their elders and the world in which they live, yet their studied attitude is one of supreme indifference to life. Julian Perryman—"spelt with a y"—is expelled from Oxford because in a night of joy he has seen fit to celebrate by pulling down a crystal chandelier. Audrey Nye, a companion of the evening's jollification, is dismissed from Somerville for an unconventional return through the window at early dawn, so the two plan a motor trip to their respective homes. Julian's car breaks down, so the two young things decide to walk to London since they "dislike trains." The respective parents are horrified to learn that their children have spent a night at an inn together, and refuse at first to believe their story about separate rooms. This is one of the most significant truths the author has expressed in the book—that normal youth, however rash and indiscreet it may be, is usually decent.

And so the reader follows Julian and Audrey through a series of adventures and experiences, including Julian's "companionship" with the pretty young wife of a neighbor, and his experiences in journalistic work, to a time when circumstances make it necessary for these young people to take the reins of life in their own hands. Their lives have taught them to do this with at least no complainings, with courage, and a certain amount of self knowledge. "We thought ourselves so jolly superior to the rest of humanity," says Julian. "We were so stuck up with ourselves. We didn't expect the ordinary knocks that come to most people. We were the superior people, highly educated, very refined, utterly sure of ourselves, contemptuous of the old people, and their fears about us, and their cautions. We were the younger generation, out for a good time, with lots of rights and no duties, and all for the liberty and adventure. Sheltered from vulgarity and passion, and able to take risks which scared our preposterous parents! In fact we were utter frauds, and rather caddish. Pretty selfish. Conceited kids! Well, we've had our heads knocked together. We've been taken down a peg or two. That's all right. It'll do us a bit of good. Anyhow, I'm damned if I'm going to whine!"

The author, perhaps wisely, offers us no solution of the problem. He confines himself to the painting of a careful and usually sympathetic picture of life in modern England, one which at least stimulates very active thought upon this vital subject of the younger generation.

Medicoliterary Notes.

The Romance of a Living Temple is a title suggestive of the contents and treatment of the subject in hand of a recent book by Frederick M. Rossiter, B.S., M.D. The subtitle is *A Study of the Human Body,* and chapter by chapter the discussion follows the analogy of the body to a temple. Such a presentation of a scientific subject may appeal to a certain type of reader, but most lay readers even will feel that the book would gain in force if the subject were more simply and directly presented.

* * *

Dr. James J. Walsh, author of many books and articles on medical subjects written especially for the layman, is lecturing at Chautauqua this summer on various topics discussed in his writings.

* * *

At the University of Wisconsin a general plan has been originated for the establishment of a national institute for research in colloid chemistry with a permanent training school where scientific workers may attack the many still unsolved problems connected with the subject. The fields for experiment will include agriculture, engineering, geology, industry, medicine, biology and physics. The application of colloid chemistry to medicine is credited with saving more than 20,000 lives during the World War.

* * *

A recent book of interest to the criminologist and the psychologist is *Studies in Murder* by Edmund Lester Pearson, published by Macmillan. It contains accounts of a number of murders committed within the past century, and of the trials, when such were held, connected with the crimes.

* * *

The knowledge and use of salt are as old as man. The use of salt for preserving foods was known to the early Egyptians and Assyrians, and the process is recorded both in the hieroglyphic and cuneiform writings.

* * *

Yellow fever has been effectively controlled by breeding fish that feed on the larvæ of the mosquitoes that disseminate the disease. This method has been utilized to good effect in Panama as supplementary to the draining of swamps and oiling of the surface of standing water.

* * *

Dr. Stanley M. Rinehart, Major U. S. Medical Corps and for many years a general practitioner in Pittsburgh, is the author of *The Common Sense of Health,* recently published by Doran. During the war Dr. Rinehart had charge of the tuberculosis work at Camp Sherman and was afterward consultant on tuberculosis in the Surgeon General's Office and in charge of all army tuberculosis hospitals. His wife is Mary Roberts Rinehart, the well known novelist.

* * *

In cooperation with the Commonwealth Fund of New York City, the Berkshire Industrial Farm, a school for the "problem" boy, located at Canaan, N. Y., is about to begin a study of conduct disorders, Dr. Clinton P. McCord, consulting psychiatrist to the Farm, who is director of the mental hygiene work in the public schools of Albany, and instructor in educational hygiene in the Albany Medical College, will visit the Farm regularly to direct the psychiatric research. . . . The aim . . . is to make an intensive study of conduct disorders with the material under prolonged observation and control. It is hoped that the work will prove of value in dealing with "problem" boys in institutions.—*Mental Hygiene Bulletin.*

* * *

The numbers of the *Living Age* for July 12th and 19th are unusually interesting. An article on Our Minutest Foes Unmasked, by Franz Schikora, an associate of the bacteriologists who have succeeded in isolating and photographing the germ of the foot and mouth disease, is quoted from the Berlin *Vossische Zeitung.* Another article quoted from the same publication and written by Wolfgang van Weisl describes the *Sacrifice of the Passover on Mount Gerzim,* the meeting place of the last few remaining Samaritans, who claim to be the true Israelites, but not Jews. Karl Federn, writing in the same paper, gives some interesting impressions of *D'Annunzio, a Prince at Sixty.* In the issue of July 19th is quoted an article by Stéphane Lauzanne on *Will French Women Ever Vote?* The writer believes the answer to be distinctly *No.* William Little is the author of an article from the *English Review* tracing the history of the alcohol problem through the ages. A sketch of the home life of the Romanoffs, by a tutor in the family, is taken from the *Dni,* the Russian journal published in Berlin, and Douglas H. Stewart, writing for the London *Outlook,* cleverly describes a visit to a "literary factory."

* * *

The Illinois State Medical Society has in preparation for publication a History of *Medical Practice in the State of Illinois,* which will go back in scope over a period of 250 years. The society is making an appeal, in order that this volume may be accurate and complete, for personal data and experiences, including photographs, diaries, and similar documentary mementoes of pioneer Illinois doctors and of progressive phases of medical practice, as well as of achievements in fields other than those of medical science. Some of the subjects treated in the history will be physicians accompanying early explorers, government physicians and surgeons in attendance at the forts, theories of healing from the days of the aborigines through the mound builders, French and English explorers, anteboundary days, sporadic settlers, medical attendants for the covered wagon, herb doctors, primitive surgery, medicine and missionaries, migration of pioneer physicians to new territory, circuit riding and saddlebag doctors, pioneers as utility citizens, and Illinois medical men in industry, science, art, music and literature.

* * *

Recent statistics show that Hungary has the lowest birth rate of all European countries.

* * *

Dr. G. V. Anrep, assistant professor at University College, London, and formerly assistant to Prof. T. P. Pavlov of Petrograd, recently delivered a lecture of unusual interest at the New School for Social Research in which he described the experiments made by Prof. Pavlov in his laboratory in connection with the conditioned reflex.

* * *

Carolyn Conant Van Blarcom, representative of the American Child Health Association, addressed the Third English-Speaking Conference on Infant Welfare held in London in July. Miss Van Blarcom is the author of *Obstetrical Nursing* and *Getting Ready to Be a Mother* (Macmillan).

* * *

The Fundamentals of Vocational Psychology, by Prof. Charles H. Griffits of the University of Michigan, recently published by Macmillan, describes the various methods used in determining the qualifications of any individual for a particular vocation, explains and criticizes the psychological principles on which these methods are based, and points out the precautions necessary to secure valid results.

* * *

A recent German government report of an investigation of money as a source of infection states that disease germs are much more prevalent among postwar bank notes in Germany than they were in paper money in use before the war because of the fact that the currency is handled much more frequently than prior to 1914, probably because there is so much less of it. The investigation showed that coined money is virtually innocuous, owing to the selfdisinfecting action of the metal itself, and because the small, smooth surface of the coins prevents development of germs.

* * *

Probably few persons, even physicians, know that the first wood engraver in America was a doctor, Alexander Anderson, who was born in New York City in 1775. He made woodcuts for *The Looking Glass of the Mind* and other well known works, and some copper engravings after Holbein.

* * *

The mental hygiene survey of Staten Island, New York, has been completed and the report is being prepared. This study included 3,042 children in three public schools—a prevocational school, a continuation school, and a large public school; preschool children in three day nurseries and in St. Michael's Home; the inmates of the Richmond County Jail, and the children in the detention home for the Society for the Prevention of Cruelty to Children. It was conducted by the Division on Mental Deficiency of the National Committee for Mental Hygiene.—*Mental Hygiene Bulletin.*

Abstracts from Current Literature

HEART AND BLOODVESSELS

Cardiology.—J. S. Goodall and L. Rogers (*American Journal of Surgery,* May, 1924) contemplate the application of surgical methods for the relief of mitral stenosis, particularly when it has reached an incurable and continually advancing stage. The patient dies solely because of the obstruction of the mitral valve. They suggest the following operation, the whole object of which is to get oxygenated blood into the left ventricle. This is theoretically possible by establishing an extracardiac connecting channel, or by opening up the obstructed mitral valve. The latter procedure may be carried out by way of the ventricle, or by way of the auricle. Points in favor of the ventricular route are: It is more superficial; the absence of pleura over part of the pericardium; a thick muscular wall to operate upon; a small quantity of blood in the ventricle until the small valve is incised; less likelihood of introducing emboli into the circulation. On the other hand, there is difficulty in finding mitral opening, e. g., the lower end of a funnel; danger of wounding auricle; danger of paralyzing or causing fibrillation of ventricle; and subsequent degeneration of part of ventricular wall owing to sutures.

Although a somewhat more difficult procedure, the writers at present favor the auricular approach, the main advantage being the comparative ease with which the mitralotomy knife may be introduced through the stenosed valve, especially when of the funnel type. That portion of the pericardial sac which may conveniently be opened to expose the left auricle, lies between the vagus and phrenic nerves and below the superior intercostal vein. Indications for operation would be deficiency of the left ventricular output as evidenced by a falling and low blood pressure; smaller volume and force of pulse; absence or reduction of T waves in Lead II, of electrocardiogram; indications of the approach of right heart failure.

Diseases of Blood Vascular System of Extremities.—B. Brooks (*Journal of Bone and Joint Surgery,* April, 1924), through a series of experiments on dogs, shows that the decreased intravascular pressure of an extremity distal to the obstruction of an artery is increased by subsequent obstruction of the primary vein of the extremity. The increase of venous pressure over arterial pressure indicates a diminished volume flow of blood through the extremity. In applying these findings to contracture, that kind in which there is a fracture, usually of the distal end of the humerus, he explains the swollen condition following the application of a bandage as the result of a total obstruction of the venous system without obstruction of the arterial system. The obstruction of the outflow of blood raises the intravascular pressure in the capillaries until there is a complete disruption of these vessels, and the reaction of the tissues is that of acute inflammatory disease, followed by extensive fibrosis of the tissue. The fact that there is no obstruction to the arterial supply is proved by the fact that a severe inflammatory process exists. In like manner he explains certain clinical phenomena of other extremity diseases, i. e., contracture from arterial obstruction followed by anemia and a rapidly developing collateral circulation, gangrene from ligature of the large arteries, and spontaneous gangrene.

In discussing the variety of gangrene in which the arterial disease is confined to a relatively small area in a large artery or to only a branch of the primary artery, viz., thrombosis or embolism of the popliteal artery, he says: "In these conditions there is a definite possibility of relief by surgical treatment. There is an adequate arterial tubage in the affected extremity distal to the arterial obstruction. The volume flow of blood is not adequate, or the intravascular pressure is not sufficiently great for an efficient distribution of the blood. The problem to be solved in such a case is to get blood through or around the obstruction or make it possible to use the blood which is getting around the arterial obstruction more successfully. To accomplish the former the arterial block must be bridged by a vessel transplant or the collateral branches must be widened. In this connection, if the operation of perivascular sympathectomy is to accomplish anything, it is my belief that the sympathetic nerves must be operated on at such a site that the result is a dilatation of the branches of artery proximal to the obstruction which supplies the collateral circulation, rather than a dilatation of the arteries distal to the arterial block. If it could be established that the volume flow of blood through or around the block was adequate for life and the intravascular pressure was too low for proper distribution of the blood, then improvement would probably follow the production of an occlusion of veins sufficient to balance the circulation and maintain a higher intravascular pressure."

In conclusion Brooks points out the need for methods of examination, the present methods of determining blood pressure being inaccurate, and all methods of determining the pressure in the pulseless artery distal to an arterial obstruction being useless. At the present time experiments are in progress to determine the possibility of studying the size of the lumen of the arterial tree by intraarterial injection of sodium iodide and x ray studies. If this method is successful, as the experiments promise it to be, then it will be possible to determine the site and extent of arterial obstruction, and it may indicate the distribution of the blood flowing through the artery injected.

It would seem that heretofore attention has been too much centred on the vasomotor apparatus. It is possible that more could be learned if the viewpoint was shifted to that in which the bloodvessels were considered as tubes. At least it is certainly more within the grasp of the practical surgeon to consider the circulation of the blood in the extremity as fluid circulating through a system of tubes than to think more or less vaguely of the phenomena of the sympathetics. Every specimen amputated for gangrene and examined by the author has shown definite mechanical blocking of the lumen of the artery, and he has never seen a clinical condition of ischemia which he could be reasonably certain was due to arterial spasm.

The Heart in Hyperthyroidism.—William Dameshek (*Boston Medical and Surgical Journal,* March 20, 1924) studied 141 cases of hyperthyroidism, with special reference to cardiovascular symptoms. Forty of these patients were considered to have damaged hearts, divided into three classes:

1. The paroxysmal arrhythmia group,—twelve patients. In these, nine had auricular fibrillation; one, auricular flutter; one, auricular fibrillation and flutter; one, auricular tachycardia; average age, 39.5 years.

2. The block group, five patients: two, paroxysmal complete block; two, delayed conduction time; one, bundle branch block; average age, 36.4 years.

3. Heart failure group, twenty-three patients, with symptoms of heart failure only. Of these, ten had auricular fibrillation (permanent). Two types were distinguished: 1, the young, full blown cases with high metabolism; 2, the oldish, mild, atypical case, usually with adenoma, and with relatively low metabolism.

Concerning these he makes the following points:

1. Forty cases with cardiac damage in 141 of hyperthyroidism represent no mere coincidence. This observation immediately puts the cardiovascular symptoms (complications, if you will) of hyperthyriodism above all other symptoms in importance.

2. All cardiovascular symptoms may well be explained by assuming that hyperthyroidism represents a toxemia of some sort, with especial predilection for the myocardium.

3. The heart which is not clinically damaged is probably one undergoing irritation from the toxin. This causes the subjective symptoms of palpitation and precordial pain and the objective symptoms of rapid and forceful action.

The presence of forceful apex impulse, thrill, loud first sound, questionable presystolic murmur suggest mitral stenosis; the presence of peripheral pulsations and "pistol shots," of high systolic pressure, Corrigan and capillary pulse suggest aortic regurgitation.

4. Damaged hearts probably represent myocardial destruction of more or less degree. a. Cases with paroxysmal arrhythmias, and with paroxysmal heart block, occurring as they do usually in younger people, show a damaged heart muscle, with, however, enough good muscle for compensation. b. Cases with heart failure, coming in persons below forty, are usually end results of a full blown hyperthyroid

ism with very marked toxic action over a short period. c. Cases with heart failure in persons over forty (usually over fifty) are usually end results of a mild or atypical hyperthyroidism, usually with adenoma, the toxic action of which has acted in small doses over a period of twenty years or more.

5. Suspect hyperthyroidism in cases showing paroxysmal arrhythmia; in young people with severe precordial pain or with attacks of palpitation; in women over forty with heart failure and thyroid adenoma.

6. Medical treatment, except preliminary to operation, has no place in hyperthyroidism. Surgery (with x ray as a poor second), by removing the source of the toxemia, is the only means for combating the disease. More attention, especially surgical attention, should be focused on adenoma of the thyroid. In middleaged persons surely, in persons over twenty probably, it should be removed surgically.

The author emphasized the paramount importance of constant watch over the heart in hyperthyroidism.

The Heart in Hypertension.—James P. O'Hare and William G. Walker (*Boston Medical and Surgical Journal,* April 24, 1924), say that the prognosis of the heart in hypertension depends upon three elements:

1. The amount of strain. This may be the strain of living, or, more specifically, the strain against which the heart is beating. The latter is indicated by the height of the diastolic pressure. This measures the tonicity of the peripheral arteries and arterioles. Given a constantly high diastolic pressure, the prognosis is poor. Usually, however, these patients die of a cerebral accident before the heart wears out.

2. The condition of the coronary arteries. It is obvious that disease of these vessels may result in a poorer nutrition of the myocardium supplied and a consequent decreased efficiency of the heart. Furthermore, the likelihood of death from angina and coronary infarct must always be borne in mind. In Janeway's cases seven per cent. died in this way. In this connection, it is worth while to reiterate what Levine has pointed out—that those cases of angina with systolic pressures around 160 to 170 are the cases most to be feared.

3. The condition of the myocardium, which may be the result of factors 1 and 2. Here the evidence pointing to a grave outlook consists of a poor response to effort, a weak first heart sound, a persistently high cardiac rate, gallop rhythm, pulsus alternans, an inverted T wave in Lead I of the electrocardiogram when a digitalis effect can be excluded, a low vital capacity, defective conduction time, heart block and, perhaps, fibrillation.

Blood Pressure and Heart Action in Sleep and Dreams: Their Relation to Hemorrhages, Angina, and Sudden Death.—J. A. MacWilliam (*British Medical Journal,* December 22, 1923), maintains that in considering the subject of sleep one must deal with two distinct conditions, which have strikingly different associations, as far as nervous, circulatory, respiratory and other functions are concerned: 1, undisturbed or sound sleep, in which the blood pressure, cardiac and respiratory rates, etc., are lowered; 2, disturbed sleep, modified by reflex excitations, dreams, nightmare, etc., which are sometimes associated with marked rises of blood pressure, increased cardiac activity, changes in respiration and various reflex effects. The circulatory changes may be very pronounced. Night is not always the time of rest and sleep. This conception, while true as regards undisturbed sleep, has to be qualified by the consideration that night and sleep are occasionally the season of acute reflex and emotional disturbances, which, in the peculiar conditions present, induce very pronounced effects on the circulatory system, throwing a formidable strain upon its weak points, whether these be cardiac, with susceptibility to fibrillation or anginal pain, etc., or arterial, with risk of rupture. In this way the individual may, during the nocturnal period of assumed repose, be subjected to suddenly developed stresses, as estimated by the rise of blood pressure and the evidences of increased heart action, far beyond what is involved in ordinary muscular exercise gradually initiated. Thus hemorrhages, the onset of anginal attacks, and other disturbances in the night can be readily accounted for; also sudden death, probably due to ventricular fibrillation in most instances.

Factors, Actual and Possible, in Cardiac Nutrition.—Frederick H. Pratt (*Boston Medical and Surgical Journal,* February 21, 1924), says that modes of nutrition to the heart have four conceivable origins: 1, The coronary stream, yielding the vastly preponderating nutrient supply; 2, the pulmosystemic stream, passing laden with nutrition over endothelial and probably highly absorptive surfaces; 3, the sinusoidal stream, a diverted portion of the above, bathing the walls of the vestigial sinusoids (trabecular clefts and Thebesian openings) and known to be capable under experimental conditions of imparting a certain quota of nutriment to the myocardium; 4, the lymphatic stream, of problematical significance in the heart, yet undoubtedly an active distributor of material such as might be absorbed from the heart cavities.

Electrocardiographic Evidence of Myocardial Involvement in Rheumatic Fever.—Alfred E. Cohn and Homer F. Swift (*Journal of Experimental Medicine,* January, 1924) report observations showing in thirty-five of thirty-seven cases of rheumatic fever that the heart was affected in one way or another. They state that the evidence was of three sorts; first, the duration of auriculoventricular conduction was increased, though not always, and not usually to the degree of causing heart block; second, alteration in the ventricular complex of the electrocardiogram affecting in certain instances the QRS complex and in others either the interval between R wave and T wave, or the T wave itself; and third, the occurrence of numerous irregularities in cardiac rhythm. These signs express derangement of the heart, but are not specific for rheumatic fever. However, they are to be interpreted as evidence that the heart is affected by the rheumatic process even though an inference cannot be drawn as to the nature or the permanence of the injury. The facts brought forward show that it is possible during the course of the disease to know whether the heart is involved in the general process.

Hyperpiesis and Arteriosclerosis.—H. Batty Shaw (*British Medical Journal,* March 22, 1924), asserts that there is no justification for bunching together all the changes in the arteries under the title of arteriosclerosis or arteriocapillary fibrosis, which, strictly speaking, is not a clinical term, but a permissible pathological one to be used to describe particular conditions in which fibrosis affects the walls of an artery in toto, or only in part. Two forms of arterial disease may be recognized clinically; namely, 1, hyperpiesic and occupational tortuosity and hardening due to hypertrophy of the media, and 2, tortuosity and perhaps hardening independent of hyperpiesis and occupation, but due to infection which causes formative inflammation of the coats of the artery, as shown by cellular proliferation and by cellular exudation. The other forms of arterial changes which may defy clinical detection are arterial degeneration affecting the intima (atheroma) and degeneration affecting the media. There can be little doubt that such degenerations are toxic in character, maybe from lead, but in many other cases the toxic material is, judging by analogy, due to bacterial infection, which instead of being formative and protective is destructive and menacing.

Cardiovascular Conditions.—Mary L. H. Arnold Snow (*American Journal of Electrotherapeutics and Radiology,* May, 1924) presents an outline and the specific instances of results obtained in the treatment of cardiovascular conditions. She has shown marked effects by her method of management in the treatment of high blood pressure and the correction of a condition upon which she lays stress—a disparity often found in patients in whom there is a higher blood pressure lying than when sitting, indicating, in the author's opinion, a dilatation of the splanchnic area. By the case reports given, the author shows that by the use of mechanical vibration applied in the cardiovascular region from the seventh cervical to the sixth dorsal vertebra, marked effects are obtained by restoring the normal relation, correcting the blood pressure and the pulse pressure in given cases. The paper closes with conclusions as follows:

1. A more careful study of postural blood pressure and pulse pressure relationship would assist in determining prognosis and treatment, especially the study of pulse pressure which indicates cardiac and arterial conditions.

2. A comparative study of the velocity of the blood in connection with that of systolic, diastolic, and pulse pressures, as well as of pulse rate, will assist in standardizing treatment.

3. A reversed blood pressure postural relationship, associated with hypertension, is corrected or aided by a five minute vibratory treatment from the second to the sixth dorsal vertebra from above downward and alternately from side to side.

4. A reversed blood pressure postural relationship, if associated with low blood pressure, as a rule, when primary, is probably best treated by a two minute vibratory treatment between the seventh cervical and first dorsal vertebræ with the ball vibratode; exceptions are generally amenable to a vibratory treatment as indicated in the preceding paragraph.

5. Hypertension without systolic disparity when not occurring secondarily with valvular disease with nephritis is usually reduced by a five minute vibratory treatment between the second and third, and third and fourth dorsal vertebræ.

6. Hypotension when primary is treated with palliation, or symptomatic cure by inducing the cardiac reflex of contraction through toning up the heart by a two minute vibratory treatment with the ball vibratode between the seventh cervical and first dorsal vertebræ. Bishop notes that "in primary low arterial tension the heart muscle is in a position to recover its tone if depleted by acute disease, or to develop a compensatory hypertrophy if overtaxed by defective valves."

Prognosis in Cardiovascular Disease.—Thomas F. Cotton (*British Medical Journal,* February 23, 1924), states that the structural damage of the heart can be estimated from the physical signs with a fair measure of exactness. The physical examination rests upon those signs which indicate heart failure, the degree of cardiac enlargement, the valve defect, the rhythm, infection, etiology and the state of the arteries. It also includes an exercise tolerance test. There are two main types of heart failure: heart failure with congestion (engorgement of the venous system) and that with angina (without signs of venous congestion), always with disease of the myocardium and unfavorable outlook. A systolic murmur, wherever heard, is an unreliable sign of heart disease. The prognosis depends on the extent of the myocardial damage and the degree of renal impairment. In advanced myocardial disease the prognosis depends more upon the condition of the heart than on the condition of the kidneys, except in well advanced disease of the kidneys. If the myocardial disease is only slight the prognosis depends upon the functional capacity of the kidneys.

Rôle of the Osmotic Pressure of the Blood Proteins in the Pathogenesis of Edema and of High Blood Pressure.—P. Govaerts (*Bulletin de l'Académie royale de médecine de Belgique,* March 29, 1924), finds that by the use of cellophane as a membrane impermeable to proteins a simple osmometer can be made permitting of the clinical study of the osmotic pressure of the blood proteins. In normal subjects the pressure, as measured with his apparatus, is about thirty-five to forty centimetres of water. The pressure is proportionate to the protein content of the serum, one gram of proteins in 100 giving rise to a pressure of about 4.61 centimetres of water. In the serum of patients with edema, a reduced osmotic pressure of the proteins is found. Further, the pressure per gram of proteins in 100 is likewise reduced. These changes may exceptionally be wanting in edema due to mechanical hindrances to the venous circulation, but whenever the pressure was below thirty centimetres of water, edema was present. The intensity and tenacity of dropsy are proportionate to the reduction of pressure, which is most pronounced in the anasarca of nephritis. In cases of high blood pressure, on the other hand, the osmotic pressure of the proteins is high and the pressure per gram of proteins in 100 is increased. The osmotic pressure is susceptible to variation according to the total protein content of the blood plasma, the nature of the proteins present, water retention, salt retention, and changes in the distribution of hydrogen ions in the blood and tissues. The fundamental condition leading to the appearance of chronic edema is a pressure in the capillaries exceeding the osmotic pressure of the proteins in the blood plasma. It may thus be readily understood that certain stasis edemas are due solely to increase in venous pressure. In all the other cases studied, the osmotic pressure was diminished; this explains why edema may appear when the pressure in the capillaries is but slightly raised or even normal. Reduced osmotic pressure of the proteins may be considered to be the essential immediate cause of various chronic edemas, whether of cardiac, cachectic or nephritic origin. On the other hand, the results obtained would not justify a conclusion that increased osmotic pressure of blood proteins is a causal factor of high blood pressure. It is, however, permissible to think that such an increase confers upon cases of high blood pressure special resisting power to the production of stasis edema. One is often surprised to find complete absence of edema of the lower extremities in cases of high blood pressure, with or without nephritis, but with obvious cardiac insufficiency. In these subjects edema scarcely appears unless the blood becomes dilute by reason of progressive renal failure and reduced diuresis. Very probably this special resistance to the production of edema is due to two factors, viz., the low peripheral circulatory current, reducing venous pressure, and the high osmotic pressure of the blood proteins.

Cardiorrhaphy in Acute Injuries.—W. R. Smith (*Annals of Surgery,* December, 1923), offers the following summary to a report of two of his cases and a tabulated report of recorded cases. Cardiorrhaphy is a comparatively recent advance in surgery. The human heart is very tolerant of manipulation. This fact has been repeatedly demonstrated, especially in connection with foreign body extractions during and since the world war. Surgical pneumothorax is remarkably well tolerated. The symptomatology of heart injuries varies widely, and as a consequence the diagnosis of this condition is often very difficult. In cases of doubt, therefore, exploratory operations are justifiable. Transpleural thoracotomy under general anesthesia is probably the procedure best suited to the average case of this type. Drainage in these cases can be accomplished best through the medium of a simple valve tube drain through the chest wall.

Aneurysm of the Renal Artery.—M. J. Conroy (*Annals of Surgery,* November, 1923), gives an analysis of all cases in the literature with a report of a case and a dissertation on the etiology, pathology, symptoms, diagnosis, prognosis, and treatment of this condition, which latter follows. For those aneurysms which give rise to symptoms, there is but one efficient type for treatment. The best procedure is apparently removal of the sac together with the kidney. Morris advocates an oblique lumbar incision at the start, and an extraperitoneal approach is made until the nature of the tumor is discovered. This can be done by nicking the sac, and if laminated clot the sac should not be penetrated further for fear of starting a profuse hemorrhage. Once the growth is proved to be an aneurysm, if small the peritoneum is reflected medially and the sac with the kidney is removed extraperitoneally. If the sac is large, a transperitoneal approach should be made by continuing the incision anteriorly. The renal pedicle should be clamped before attempts are made to free the sac from surrounding structures. When this has been accomplished, the renal vessels and ureter are ligated, the pedicle severed distal to the ligatures and tumor and kidney removed in toto.

Preoperative Digitalization.—S. H. Geist and M. A. Goldberger (*Annals of Surgery,* December, 1923), report on a series of a hundred cases in which digitalis was used to combat fall in pressure of postoperative shock. They describe their method of administration as follows:

"At the time of the publication of the original paper we used two methods, the slow and the rapid method. We have found that the slow method had certain advantages, namely, ease of administration and absence of the digitalis nausea and vomiting, and for these reasons, of the hundred cases in the second series, all but eight were digitalized by the slow method. In the slow method digitan tablets, each one and one half grains, were used instead of the standardized tincture of digitalis. We give one tablet of digitan to each fifteen pounds of body weight as the total amount. The first dose is given twenty-four hours before operation and then every two hours until the entire amount is taken. On the morning of operation two more such doses at two hour intervals are given and occasionally twelve hours postoperative or twenty-four hours postoperative another dose can be administered. Digitan is standardized by its manufacturers, one and one half grains being equal to fifteen cc. of the standardized tincture. The digitalization effects last ten to fourteen days, so that if operation is deferred a few days, patients should not be redigitalized.

as in such instances one may get nausea and vomiting or other distressing symptom of poisoning.

"Comparing our results in this series with any random group of nondigitalized cases we feel that it confirms all the advantages previously claimed. It would seem, therefore, that it would be a decided advance to use this method as a routine for operative preparation just as much as the shave, tub, enema and morphine. The method is simple of execution, accurate in dose and nontoxic in its effect if the directions are followed."

Absorption of Adrenalin.—D. Murray Lyon (*Journal of Experimental Medicine,* December, 1923) investigated the response to hypodermic injection of adrenalin in fifty patients. The effects of the drug included a rise and subsequent fall in the volume of expired air, the oxygen consumption, the carbonic acid output, the metabolic rate, the respiratory quotient, and the systolic blood pressure. The movements of these readings coincide closely, and the record of the systolic pressure changes may be taken as expressing the general reaction. From this study Lyon draws the following conclusions: Adrenalin solution, given subcutaneously, is usually rapidly absorbed, probably by lymphatic channels. The speed of the process may be influenced by the circulation rate. The relative amounts of adrenalin at any moment unabsorbed at the site of inoculation, carried in the circulating fluids, and taken up by the reacting tissues can be calculated from figures extracted from the curve of the blood pressure changes. The relative rates of transference of adrenalin into the blood and from the circulation into the tissues can also be estimated. When absorption takes place rapidly a large quantity of the drug comes into action at once and the maximum occurs early, the curve of blood pressure reaches a considerable height, and subsides quickly. When absorption is slow the apex appears later and does not reach so high a level. The response to adrenalin bears a logarithmic relationship to the dose employed and a method of allowing for this is indicated.

Diagnosis and Treatment of Cardiac Neuroses.—Francis W. Peabody (*Northwest Medicine,* March, 1924), says that the treatment of cardiac neuroses is as easy to outline as it is hard to carry out. It consists essentially of mental hygiene and physical development. The former is the more important and much the more difficult for doctor and for patient. First of all it is necessary to get away from the idea of physical invalidism and particularly from the idea of heart disease. One of the most effective means of doing this is by making an extremely careful physical examination, including in it the use of the modern instrumental methods which may throw light on the condition of the heart. The psychological effect of a complete, thorough examination cannot be overestimated, and it is extraordinary to see how often a patient will respond to it and will accept the verdict that he is physically sound.

The next step is to convince him still further by making him take gradually increasing amounts of exercise and by showing him that not only is he uninjured but that he is benefited by it. The patient's attention should be directed to improving his general condition and not to improving his heart. Beyond this it is necessary to procure an interesting and if possible absorbing occupation. One cannot lay too much stress on the importance of regularity of work, of accuracy in performing all technical procedures, and of completing everything that is undertaken. The natural tendency to do things halfheartedly and to avoid concentrated effort must be overcome. It is essentially a problem of character training, and sometimes the problem is as difficult as that of transplanting vertebræ into the spineless jellyfish.

The significance of physical development in the symptom complex of cardiac neuroses was clearly indicated by the results of tests of muscle strength carried out by Dr. Bernard Smith at the Lakewood General Hospital. These tests consisted of measurements of the pull against a spring balance of various muscle groups, according to the method of Martin, and they were applied to large numbers of normal soldiers as well as to soldiers with cardiac neuroses. The average strength test of normal young men was found to be expressed by the figure 25, while that of the patients with cardiac neuroses, and particularly of the group which corresponds to those seen in civil life, was 12. The muscular strength of the patients was, therefore, only about fifty per cent. of the normal.

In the consideration of fatigue it is extremely difficult to differentiate between the purely muscular factor and the mental factor which is associated with it, but the manner in which physical exercises improved the strength tests make it certain that the muscles themselves are not to be neglected. After being put through carefully supervised, graduated exercises many of the patients who had low strength tests were brought up into the normal class. Together with the physical development went a mental and moral development. Physical exercise bred selfconfidence, and with self-confidence came the ability to look at the world from a more normal and sane point of view. Sometimes it is extremely difficult to make these patients with cardiac neuroses undertake any physical exercise because they dislike it and fear its effects, so it must always be carried out under sympathetic but strict supervision until a complete selfconfidence has been obtained. The problems of mental and physical training in the treatment of the cardiac neuroses are difficult and time consuming, and they require a physician with a personality that is specially adapted to them if they are to be carried out successfully. The results that may be attained, however, are well worth the effort that goes into them.

Water Excretion as Influenced by Blood Pressure Response to Sodium Nitrite.—Edward C. Mason (*Journal of Laboratory and Clinical Medicine,* May, 1924), undertook the investigation reported in order to determine whether sodium nitrite altered the urinary output sufficiently and frequently enough to warrant the withdrawal of nitrites during a water test, and whether the urinary response paralleled the blood pressure response. The patients studied were loosely classified in four groups: those with hypertension and nephritis; those with hypertension without nephritis; those with nephritis without hypertension, and those with normal blood pressure without nephritis. In twenty cases studied, sixteen patients had a decreased urinary output with sodium nitrite, the decrease ranging from 1240 c. c. to as low as 58 c. c. The administration of sodium nitrite lowered both systolic and diastolic pressure, but the decrease in systolic pressure was commonly more marked than that of the diastolic. This unequal lowering of blood pressure produced a decreased pulse pressure. Sodium nitrite can alter urinary excretion in only two ways: by peripheral dilatation in the kidney, and by lowering renal blood pressure. The following conclusions are presented: sodium nitrite alters the urinary output sufficiently and frequently enough to warrant its withdrawal during a water test. The urinary response to sodium nitrite does not parallel the response of systolic blood pressure or of pulse pressure.

Effect of Methyl Guanidine on the Blood Pressure.—Ralph H. Major and Walter Stephenson (*Bulletin of the Johns Hopkins Hospital,* May, 1924) noted in dogs injected in the femoral vein with methyl guanidine nitrate and methyl guanidine sulphate at first a slight fall in blood pressure, followed by a sharp rise, then a more gradual rise, reaching its maximum in from ten to twenty minutes. As striking as the prompt rise was the persistence of the high blood pressure, the second maximum being maintained until shortly before death. It is suggested that methyl guanidine, a product of metabolism, if produced in excess or if not excreted by the kidneys, might cause a rise in blood pressure.

Auricular Fibrillation.—W. Dock and S. A. Levine (*American Journal of the Medical Sciences,* May, 1924), comment as follows upon their cases. Regular ventricular rhythm with a rate over fifty-five a minute occurred under digitalis treatment as a transient phenomenon in about two per cent. of 614 cases of auricular fibrillation. Attempts were made unsuccessfully in three cases to vary the ventricular rate by vagal stimulation or vagal inhibition (atropine). There is no proof that this mechanism is due to constant partial block similar to that of regular ventricular rhythm in auricular flutter, although this remains a possibility. There seems to be definite evidence that digitalis in many cases accelerates the dissociated ventricle.

Effect of Acetylsalicylic Acid on Cardiac Irritability.—W. L. Mendenhall and Harriette F. Camp (*Boston Medical and Surgical Journal,* February 21, 1924), say that acetylsalicylic acid has a stimulant effect upon the heart muscle, as indicated by a lowering of its threshold upon electrical stimulation. Its stimulating effect is directly upon the heart muscle, and is not due to paralysis or inhibition of the vagus mechanism. The drug is depressant to the heart muscle only in concentrations much higher than is likely to occur even in enormous doses of the drug.

Medicolegal Notes.

"VACATION" WITHIN MEDICAL PARTNERSHIP AGREEMENT.

A partnership agreement between doctors contemplated that if any member of the partnership took a vacation for more than six weeks in any one year, he should suffer a reduction of income accordingly. A vacation of six weeks was provided for each partner "without any deduction being made from his part of the fees and profits for the year." The Montana Supreme Court, Kettlekamp v. Watkins, 225 Pac. 1003, applying the ordinary and popular definition of the word "vacation," as "an intermission of procedure; a stated interval in a round of duties or employment; freedom or relief from duty" to the present case, holds that vacation clearly includes absence from the duties of the partnership from any cause, and would include absence from the business on account of sickness. The agreement was held to contemplate a final division of the profits at the end of the year and not oftener, and periodical divisions without reference to the time each partner was absent were held to be advances, and not a construction of the contract as entitling members to a longer absence than six weeks without deduction.

RELATIVE POSITIONS OF PARTY FIRING AND DECEASED NOT DETERMINED BY DIRECTION OF GUNSHOT WOUNDS ALONE.

The California Court of Appeals holds, People v. Salaz, 225 Pac. 777, that it was error to permit a medical expert to testify that he could "positively state," in a murder case, that the person who did the shooting was in front "and towards the left," and that "he was not immediately in front, but what we might call diagonally towards the left and in front of deceased." The court said that the question whether the direction of a gunshot wound in the body of a deceased indicates the relative positions of the person firing the shot and the person receiving it is not a matter of expert opinion evidence, and it has been held by the California Supreme Court that it is error to allow a physician to testify to his opinion upon that question. There were other factors besides the course of the bullets in the body which must be looked to in order to determine the relative positions of the accused and the deceased in the present case when the shots were fired; and the question was for the jury from a careful consideration of all the evidence.

ACCIDENT FROM X RAY RAISES NO PRESUMPTION OF NEGLIGENCE.

The Pennsylvania Supreme Court holds, Nixon v. Pfahler, 124 Atl. 130, that the rule that an action against a physician for malpractice can be sustained only by proof of his negligence, and that the burden of such proof rests upon him who asserts it, is not changed because the practitioner uses an x ray instrument. The plaintiff, while having x ray photographs taken of her teeth in defendant's offices, was injured by an electric spark which struck her right knee and passed down and out at her foot. What caused the electric current to leap from the wire through the air to the patient's leg, as it seemed to have done, was unknown; and there was no evidence that such an accident could have been anticipated, or that it resulted from any fault of defendant.

"The x ray machine," the court said, "is indispensable to the healing art, and the mere happening of an accident from its use creates no presumption against the instrument or its operation. It is necessary for those engaged in the medical profession constantly to employ dangerous agencies, like electricity, radium, surgical instruments, poison, anesthetics, etc., and if prima facie liability attaches for an accident resulting from the use of one, logically it should from the use of any other, and the practitioner employing such would be practically an insurer of the safety of his patients, which the law declares he is not. The question of liability does not hinge upon the dangerous character of the agency employed, but upon the manner of its use, as to which the presumption of due care is in favor of the practitioner, until overcome by evidence to the contrary."

ADMISSIBILITY OF X RAY PHOTOGRAPHS IN EVIDENCE

If the correctness of x ray photographs is established by the testimony of the person making them, or if they are identified by the surgeon under whose general direction and for whose use they were made, and by whom they were used in the diagnosis of the bodily injury, they are admissible in evidence.—Robinson v. Payne (N. J.), 122 Atl., 882.

PETITION FOR SERVICES TO THIRD PERSON

In an action to recover for medical services, medical supplies and nursing rendered by plaintiff to a third person, the petition alleged a liability of defendant on the theory that the third person was a dependent member of defendant's family, and that defendant was legally and morally responsible for necessities furnished her. The Texas Court of Civil Appeals, Powell v. McGee, 258 S. W., 257, held the petition defective for failure to allege the facts of dependency.

ANESTHETIST NOT LIABLE FOR CARELESSNESS IN OPERATION

The Kentucky Court of Appeals holds, Jett v. Linville, 259 S. W., 43, that, since it is a well established rule in surgical operations that the anesthetist is directly chargeable with the physical condition of the patient in the operating room, and his attention must always be directed solely to administering the proper amount of the anesthetic and continuing its supply in just such proportions as will insure the patient's remaining in a comatose condition while the knife is being used, he cannot be held responsible for any alleged carelessness in the operation, in which he did not take part.

NEGLIGENCE CAUSING INJURY

In an action for malpractice in reducing the dislocation of plaintiff's right arm, injured in an accident, the Oklahoma Supreme Court found, Ballaine v. Drake, 224 Pac., 947, that there was nothing in the evidence tending to show that any character of treatment would have effected a cure of the arm, or that any mode of treatment would have procured better results. Although upon the trial the plaintiff proved that her arm was useless, there was no attempt to show that this condition was due to the lack of skillful treatment, or that there was any treatment known to the science of medicine or surgery that would have relieved the situation. The plaintiff's case amounted to this: She received the injury, employed a physician and failed to recover. The jury could not say from the evidence whether the condition of the arm was due to the character of the injury or to the want of skill and care in treating it. In order to recover damages from a physician for want of proper skill and care, the plaintiff has the burden of showing that the defendant was unskillful or negligent and that the injury complained of was produced by such want of skill or care. There being a failure of such evidence, and no claim that the defendant guaranteed a cure or contracted for extraordinary skill or care, judgment for plaintiff was reversed.

And Now---for the Weak and Convalescent,

with the heat and humidity of the Summer months at hand, the value of a reconstructive tonic as efficient in action and as palatable and pleasant in effect as

Gray's Glycerine Tonic Comp.

(*Formula Dr. John P. Gray*)

becomes more apparent than perhaps at any other time of the year.

It is in the case of the elderly and infirm—especially those whose digestive organs are inactive and need aiding—that this tonic has shown its superiority to other restorative remedies.

Medical men who derive their greatest satisfaction from the success of the remedies they employ, will find that Gray's Glycerine Tonic Comp. will give them uniformly gratifying results as a tonic restorative when other measures prove to be uncertain and disappointing.

A liberal amount for testing the foregoing will be sent to any practitioner on request

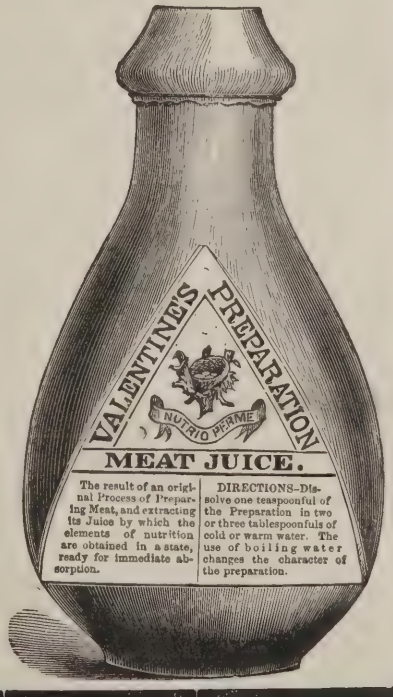
Valentine's Meat-Juice

In **Typhoid, Gastric** and **Other Fevers,** where it is **Essential** to **Sustain** the **Patient** without **Irritating** the **Weakened Digestive Organs, Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** of **Restoring** and **Strengthening** when **Other Food Fails.**



VALENTINE'S
PREPARATION
NUTRIO FIRME
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS–Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

J. R. Wood, M. D., *Physician Sheltering Arms Hospital, Paint Creek, W. Va., U. S. A.:* "I have been using VALENTINE'S MEAT-JUICE in the treatment of Typhoid Fever cases in the Sheltering Arms Hospital, for the last two or three weeks, with the most gratifying results both to the patient and physician. I consider it the best preparation of animal food I have ever seen, in fact, the only one I have ever had any success with."

Dr. Genevaix, *Assistant Surgeon-Major, First Class, Hotel Dieu, Creusot, France:* "The patients to whom I have given the excellent preparation, VALENTINE'S MEAT-JUICE, have found their general condition rapidly improved by it, and in the convalescence from continued Fever (Typhoid and Para-Typhoid) it gives the best results."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
Richmond, Virginia, U. S. A.

Miscellany.

Insanity and Art.—Comparatively few people know that lunatics paint pictures, hold their own exhibitions, and even have their work hung at the Royal Academy, says the London *Lancet*, July 19, 1924. These and many other interesting facts were told to the Art Lovers' League by Dr. T. B. Hyslop at Leighton House on July 8th, in a lecture entitled Disease in Modern Art. Dr. Hyslop, an artist as well as an alienist, confined his remarks almost entirely to the work of certified lunatics and showed a remarkable series of slides prepared from pictures which he had collected at Bethlem Hospital. Many of these illustrations showed no signs of disease, while others were mere jumbled masses representing people and other objects. One patient produced quite pleasing studies, but left out the faces of all his models. The progress of cerebral lesions was demonstrated in several sets of pictures. In one all objects became gradually more and more elongated, while in another the artist started by cutting the corners off his paintings and finally drew everything in circles which slowly diminished in size. At the close of his lecture Dr. Hyslop presented his valuable collection of lunatics' pictures and lantern slides to the Art Lovers' League.

Abuse of Tobacco.—The symptoms of tobacco abuse take many forms and are often overlooked, says an editorial writer in the *Medical Press and Circular* for August 6, 1924. Acute nicotine poisoning is characterized by headache, giddiness, vomiting, loss of appetite, and general nervous symptoms; but in addition there may be arrhythmia, pharyngitis, tremors, sweating and constipation. In chronic poisoning emaciation is a prominent symptom, accompanied by vague gastric troubles, the localization and periodicity of which lead to various errors of diagnosis. In younger and middle life palpitation and cardiac irregularity are frequently met with, and in later life angina is common. In the x ray picture the size of the heart is usually normal, but the aorta is seen to be enlarged and arteriosclerosis is probably often the result of tobacco abuse. There is also a socalled typical intermittent limping which has been observed in elderly patients, accompanied by sciatic and crural neuralgia. Respiratory catarrh is frequent, urticaria is occasionally met with, and women often exhibit migraine from cigarette smoking. The treatment for tobacco poisoning is prohibition, complete and permanent. In hypertension potassium nitrate and nitrate have given relief, and these drugs have also removed the limping. But the smallest quantity of tobacco will bring back the symptoms.

The Study of Ants.—The solution of the problem of tropical agriculture lies in the control of ants. The average dweller in the Temperate Zone has no conception of the ravages which are committed by the many species, particularly the termites, or white ants. Fenceposts, the underpinning of houses, in fact any wooden structure are devoured by them while the cutleaf or umbrella ant will clean out a garden in a single night so that nothing but bare stocks remain. Recently Dr. Thomas E. Snyder, forest entomologist, Mr. James Zetek, specialist in tropical entomology, and Ignacio Molino, entomological assistant, all from the United States Department of Agriculture, went to Naranjal, midway between Pacora and Chepo, for the purpose of studying the white ant nests there. These termitaria are hard white mounds about six or eight feet high and approximately four feet thick at the base. In the vicinity of Aguadulce, they are even larger, rising as cones to the height of about twenty feet, and giving the field or sabanas in which they are raised the appearance of an Indian camping ground with outspanned tepees. The species which makes these large mounds is known as *Amitermes nedius*. It lives on woody roots and fence posts, digesting the wood so thoroughly that nothing organic is left. To the inorganic residue they add earth and siliceous matter and build it into a cone which rapidly hardens to the consistency of soft stone. The interior of the cone contains living compartments and store rooms. The "soldiers" of this species are provided with curved, sharp mandibles which they use for defense purposes most effectively.

Dr. Snyder came from the United States recently for the purpose of carrying on research regarding the various preparations which have been used as wood preservatives in an endeavor to discover something which will protect wood against the onslaught of white ants. Once started on a building or a piece of furniture nothing now known will stop them until the wood is completely destroyed. At the zoological laboratory on Barro Colorado Island, stumps of wood have been driven into the ground and treated with various chemicals. Observations are being made on the effects of the various preparations studied and the length of time in which the ants will destroy untreated stumps. Inasmuch as there are no less than thirty different species of ants on the Isthmus of Panama, there is a tremendous field for their study here.

The Rights of the Child.—By the present Declaration of the Rights of the Child, commonly known as the Declaration of Geneva, men and women of all nations, recognizing that mankind owes to the child the best that it has to give, declare and accept it as their duty that, beyond and above all considerations of race, nationality or creed:

I. The child must be given the means requisite for its normal development, both materially and spiritually.

II. The child that is hungry must be fed; the child that is sick must be nursed; the child that is backward must be helped; the delinquent child must be reclaimed; and the orphan and the waif must be sheltered and succored.

III. The child must be the first to receive relief in times of distress.

IV. The child must be put in a position to earn a livelihood and must be protected against every form of exploitation.

V. The child must be brought up in the consciousness that its talents must be devoted to the service of its fellowmen.

The Declaration of Geneva has already received many adhesions, and it was broadcast, for the first time, on November 21, 1923, from the Eiffel Tower (Paris), the speaker being M. Gustave Ador, ex-president of the Swiss Confederation, president of the International Red Cross Committee, and one of the patrons of the Save the Children Fund International Union.

An Effective Remedy *for* Nervous Sleepless Patients

Neuronidia

Palatable Well-Tolerated Reliable

Allaying Restlessness and Producing Refreshing Sleep

Especially indicated in insomnia from mental strain, neurasthenia and other neuroses; also an excellent sedative in sea-sickness.

Diabetes Death Rates.—Interesting statistics concerning diabetes death rates and the geographical distribution of the mortality from the disease have been compiled from the 1923 mortality records of approximately fifteen million policyholders of the Metropolitan Life Insurance Company.

The lowest diabetes death rate among American and Canadian urban industrial populations prevails in the Western Provinces of Canada. For this section, the death rate was only 8.2 per 100,000. Among the 17,000 industrial policyholders in the Province of Saskatchewan not a single death from this disease occurred in 1923. Very low mortality from diabetes was observed also in the Mountain States, the Eastern Canadian Provinces (except Nova Scotia and New Brunswick) and in the Pacific States. The mortality in the East South Central, the West North Central, the West South Central, and the East North Central States, is below the average for the country as a whole, but there are certain States in each of these geographic divisions which show high diabetes rates. Above average mortality was also recorded in Maryland, the District of Columbia, Florida, Wisconsin, and West Virginia. Very low rates were registered for North Carolina, South Carolina, Arkansas, Tennessee, and Kansas.

The highest diabetes mortality in any geographical division was that for the Middle Atlantic States (20.8 per 100,000), followed by New England (17.3). The highest rate for any single State was that for Maryland (23.5), closely followed by New York (23.1), Rhode Island (20.5), and Connecticut (19.4). All of the three Middle Atlantic States, New York, New Jersey, and Pennsylvania, recorded diabetes death rates well in excess of the average for the United States.

In general, the mortality is higher in the Northern States than in the Southern. There is an important racial factor involved in diabetes. The above average mortality in such States as New York, New Jersey, Pennsylvania, Connecticut, and Rhode Island, is very possibly due to the relatively large percentage of those of foreign race stocks, more particularly Jews and Irish, who are very susceptible to diabetes. Ordinarily, the lowest rates will be found in those States which have relatively small numbers of foreign race stocks. When there are exceptions to this, it is because the States have large numbers of elderly people in their populations. Such States would naturally suffer high mortality from diabetes, because the death rate for this disease rises with advancing age.

These comparisons relate to white persons only. The death rates for the colored urban wage earners, however, are more than usually instructive because they show that there is by no means so great a difference between the diabetes death rates of white and colored wage earners as is shown for the two races in the general population. It is a well known fact that, as a group, whites suffer higher mortality from diabetes than do colored persons. In the United States Registration Area, which is about half rural, the white diabetes death rate, year after year, approximates twice that for the colored. No such margin prevails among the wage earners. In this industrial group as a whole, the white diabetes death rate exceeded the colored by only thirteen per cent. In certain geographical divisions like New England, the Middle Atlantic, the East North Central, the South Atlantic, and the East South Central States, the margin is much smaller, and in quite a number of States, notably Massachusetts, New York, Ohio, Wisconsin, Minnesota, Kansas, Virginia, North Carolina, South Carolina, Alabama, and Oklahoma, the mortality rate of the colored exceeds that of the whites—in some cases by very large margins.

The League of Nations and Malaria.—Malaria has increased to a very serious extent in Southeastern Europe since the war. This fact and the world scarcity of quinine are the two important problems on which the health organization of the League of Nations is at present engaged. The Governments of Albania and Greece requested that League commissions be sent to their countries to study prophylactic measures. Commissions are now in both of these countries and a similar inquiry will shortly be carried out in Persia in response to an appeal for technical aid from the Persian Government. According to the Greek Ministry of Health, two million persons, or about one third of the total population of Greece, are suffering from malaria. A special service has been organized to give quinine treatment to three hundred thousand chronic, for which nine tons of quinine will be required. Last February the Government had only half a ton at its disposal. The latest report, says a correspondent of the London *Times*, May 5th, from the Sanitary Council of Persia, calls attention to the appalling sanitary conditions in that country. This news is of special international importance, because a number of pilgrims cross Persian territory. According to the report, recurring epidemics of cholera, plague, relapsing fever, smallpox, typhoid, typhus and malaria, lasting sometimes several years, have occurred throughout Persia during the past eleven years. Of these diseases malaria is the most widespread and probably the most serious. In certain districts it has been so severe that whole villages have had to be abandoned. Southern Russia is another centre of infection. In the Ukraine alone 446,873 cases of malaria were reported during the first ten months of 1923, and local statistics show that only two thirds of a ton of quinine was available for distribution. The latest figures furnished by the health authorities of the Russian railways and waterways show that the situation south of Moscow is very serious, the most heavily infected districts being Turkestan, the Volga and the Caucasus. The number of malaria cases reported on the railways during the first eleven months of 1923 was 438,693, an increase of seventy-six per cent. over the previous year, while the waterways accounted for 128,789 cases, or seventy-five per cent. more than in 1922. Altogether 1,800,000 cases of malaria have so far been registered in Russia. It is possible that the problem of increasing the world production of quinine may shortly be made the object of an international conference, which would also consider establishing depots of cinchona seeds to meet the needs of the countries requiring quinine. The problem is not only one of quantity, but also of price, which has been at least quadrupled since 1914. The conference if held would therefore be faced with serious problems.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Decrease of Syphilis.—Everyone who has seen patients for the past twenty years at the out patient department of a hospital must have noticed the great decrease that has taken place in the numbers of cases with open syphilitic lesions. Gummata are becoming rarities. Dr. Paul Salmon, of the Pasteur Institure, recently published an article in the *Revue d'Hygiène,* entitled The Disappearance of Syphilis. Reports from many cities in France confirm the fact that the disease, if not disappearing, is rapidly diminishing. According to Dr. Carles, the number of infected women in Lyons decreased one third from 1911 to 1921. Syphilis, of course, is treated much more efficiently than formerly. Dr. Salmon believes that prostitution seems to be reducing the number of its recruits. In these times of economic stress, it is more difficult for the prostitute to make a living. Prostitutes have raised their rates, which has resulted in decreasing patronage. Then, professionals have a vast amount of competition. Since the war, the number of salaried women resorting to immorality to supplement their income has increased, and many women of this class have replaced professional prostitutes. Syphilis was common among public women, but it is rare among these young working women. On the other hand, it must not be forgotten that war eliminated two million men in the most active period of their lives. And the war was followed by an "epidemic" of marriages, which withdrew from circulation, as it were, many potential victims of syphilis. Finally, the army returned to civil life syphilitics, to be sure—but syphilitics who had had intensive treatment. Thus, military medicine, during the war, played an effective prophylactic rôle. Salmon concludes that, to eradicate syphilis, the most important thing is to perfect the treatment and make it truly sterilizing, such as Ehrlich planned. But medical treatment will not alone suffice. Treatment from a moral and social angle is needed. Prostitution is a reservoir for the virus. We must therefore concentrate our efforts on reducing prostitution. The hospital prison of Saint Lazare in Paris is to be demolished. Salmon says that, instead of building a new hospital prison and retaining police supervision of prostitutes, it would be better to use that money to finance a crusade against prostitution, and to come to the aid of prostitutes, who are often the victims of wretched economic and social conditions. (*Medical Press and Circular,* July 18, 1924.)

Delaware Health Education.—The Vocational Home Economics Department of the Delaware State Department of Public Instruction has for the past two years carried on a nutrition program in the public schools, according to the August *Bulletin* of the National Tuberculosis Association. A method has been worked out that can be used in conjunction with other forms of work for the undernourished child in which there is definite medical supervision. The following is a summary of the report for 1923: 1,247 children eight per cent. under weight were taught the rules of proper nutrition. 1,015 of these children gained 2,660 pounds in twelve weeks, averaging 2.6 pounds per child. 146 children lost an average of 1.0 pounds. This was probably due to the epidemic of measles, influenza and colds. 154 children attained normal weight, which means that they were helped to average health and resistance.

Consideration of Familial Diseases of Locomotion*

ALFRED GORDON, M.D.
Philadelphia

The term familial diseases implies that certain pathological states repeat themselves in several members of the same family, run an identical course and develop independently of exterior causes. Therefore they do not include epidemic diseases caused by microorganisms which may affect members of the same family, such as acute anterior poliomyelitis or encephalitis lethargica. They do not include syphilitic disorders which may attack several children but which were transmitted by the parents by virtue of an intrauterine infection from an outside microbic agent. They do not include congenital anomalies resulting from general or local diseases of the fetus, which have their effect on the growth and development of the entire fetal organism or of a part of it. Familial disorders are disorders of the germ plasm itself: the ova or the spermatozoides contain in themselves originally a latent morbid taint which leads to the evolution of an abnormal type.

In presence of any given anomaly it is highly important to determine with precision whether it is morbid and the result of an accident in the life of the fetus or else it is inherent and hereditary. In the first case the damage is confined to the carrier of the anomaly and will no more be likely to be transmitted through heredity than any lesion which occurred in the extrauterine life. In the second case, on the contrary, the affection is inherent and belongs to the group of etiological factors that are capable of exercising their influence on subsequent generations. Familial diseases, therefore, constitute a problem of heredity.

If one draws a parallel between disorders transmitted to the descendants with those present in the ascendants, almost invariably a similarity in the form is found. For example, arrested development in the intellectual domain finds its source in an analogous condition of the ascendants. Various psychic disorders of the psychoneurotic individuals originate chiefly in a similar psychic heredity, demonstrating thus the existence of disturbances of the same character in the ascendants. In physical heredity one observes a predisposition of an organic character, such as cerebral congestion, headaches, apoplectiform insults, cerebral fatigue, abnormal impressionability of the cerebral neurones to toxic factors, precocious senility by virtue of a specially transmitted power of cerebration. There are therefore substantial reasons for admitting that heredity generally speaking is expressed by transmission of similarity, and more in the fundamentals of the latter than in its form. If sometimes we do observe dissimilarity of the transformation in hereditary characteristic units, we are dealing in reality only with apparent changes of form but not of basic elements. The latter are the source of the cardinal hereditary phenomena irrespective of their form. What is commonly called predisposition in morbid functions of a physical, intellectual, moral, emotional or volitional domain, is the predominant feature transmitted directly by the fundamental psychopathic or physical disorders of the ascendants.

The most illustrative examples of such occurrences we find in the familial diseases, since, as it was already mentioned, pathological conditions are observed in several members of the same family independently of all external causes.

Myopathies which were first described by Duchenne de Boulogne in 1861, are a type of familial diseases. Cases have been described how a muscular dystrophy of facioscapulohumeral variety, with its progressive invasion of the upper and lower extremities, also of the thorax, has been observed in brothers, sisters, and cousins. This same affection may appear in subsequent generations, either in the children of the affected persons or even in the offspring of some brothers or sisters who happen to remain normal and escape the invasion of the defect. We are now in possession of facts showing that almost all apparatuses of organic life are susceptible of presenting disorders and lesions characteristic of familial diseases.

To Charcot and his pupils belongs the merit of observing a family character in some diseases of the cerebrospinal system. Familial diseases of the locomotor system were the first studied and they are the best defined at the present time. The best examples of this group are found in ataxia of Friedreich's type and of Marie's type.

Friedreich's ataxia is characterized by incoordination of movements of the tabetic and cerebellar type, by choreiform muscular instability, by intention tremor, loss of tendon reflexes, nystagmus and finally by deformities of the spine (scoliosis), also of toes,

*Read at a meeting of the Eugenics Research Association held at Cold Spring Harbor, Long Island, June 14, 1924.

Copyright, 1924, by A. R. Elliott Publishing Company.

which are in hyperextension. Anatomically one finds a posterolateral sclerosis, atrophy of the cells of Clarke's columns, of the direct cerebellar tract, of the anterolateral tract and of the posterior roots. This affection is familial, is observed in some members of the same family irrespective of the sex.

In Marie's type one finds incoordination of movements of distinctly cerebellar type in the lower and upper extremities, intention tremor, disturbances of vision due to optic atrophy and contraction of the visual fields, increased tendon reflexes. Anatomically there is a manifest atrophy of the cerebellum especially of its lateral lobes, diminution of Purkinje cells, but there are no sclerotic or inflammatory lesions; the spinal cord as well as the brain are intact. The family character of this disease is striking. In Sanger Brown's case for example five generations of one family investigated contained fifty-five persons, of whom twenty-one were affected. Not all generations were equally involved. It is interesting to note the variety of the ages at which the affection commenced to show itself in this case. The age of forty-six persons was in the first generation, forty in the second, twenty in the third, fourteen in the fourth.

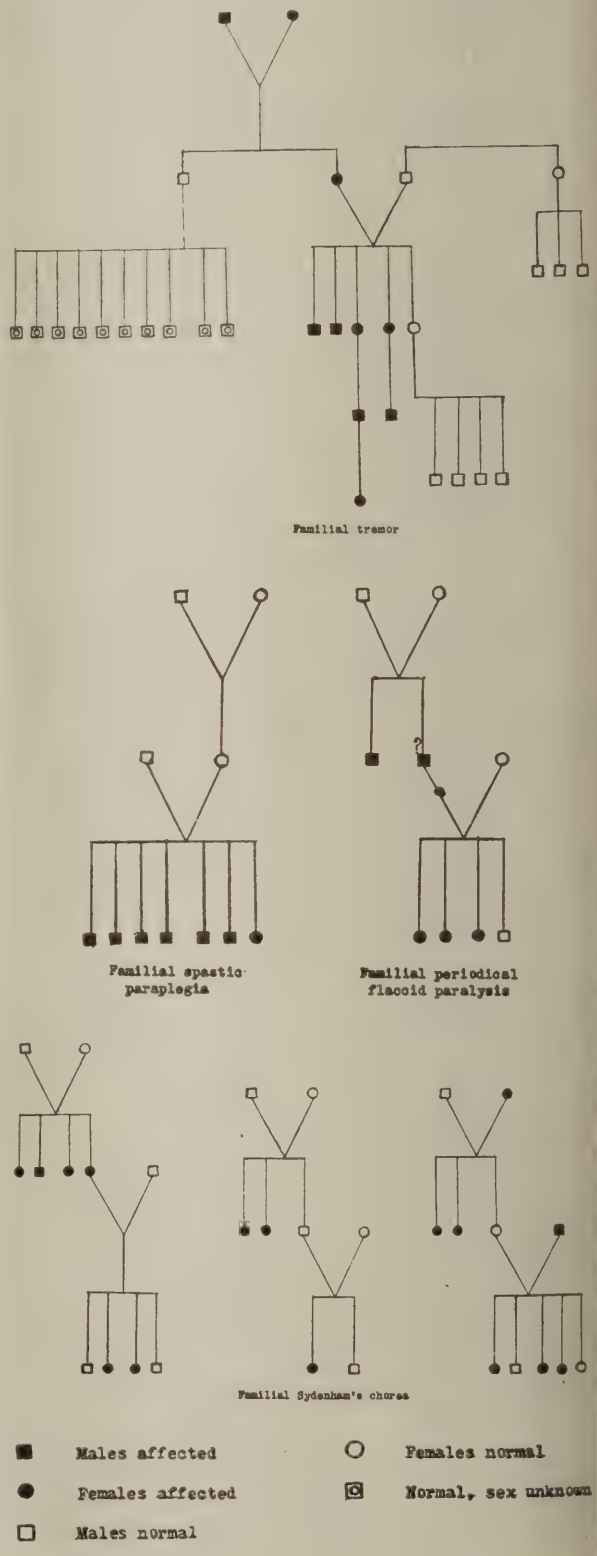
Familial atrophy of the cerebellum, as well as of the pons, medulla and cerebellar peduncles without sclerosis, was observed by Bourneville and Crouzon. During life there is rigidity of all the four limbs and extremely low grade of mentality.

In amaurotic family idiocy besides the mental arrest and optic atrophy with the characteristic spot in the retina there is also a spastic or flaccid paralysis of the extremities. The pyramidal cells of the cerebral cortex are more or less atrophied in this affection.

Muscular atrophy is another affection which may be encountered in several members of the same family. Although the classical interpretation distinguishes three types, viz., myelopathy, myopathy, and primary neuritic atrophy, nevertheless there are intermediary forms which partly belong to one or another group. A family character may be observed in any of the forms or groups of muscular atrophy. For example, in the case of primary neuritic type (Charcot-Marie) recorded by Dubreuilh, the mother and fifteen brothers and sisters were affected. In Déjérine's case the same type was observed in the grandfather, grandmother, mother, son and a brother of the mother; in Hoenel's case of the same type twenty-five persons in four generations were found. In this form the atrophy begins in the peroneal group of muscles and gradually gains the other extremities. The anatomical substratum is seen in atrophy of the peripheral nerves, degeneration of the posterior columns and of the cells of the anterior cornua.

Hoffmann's form of muscular atrophy is seen in successive children of the same mother or father. It commences early in infancy and particularly around the roots of the limbs. Gradually it keeps up its progressive course and when it invades the respiratory muscles, life is threatened. Anatomically there is a destruction of the cells of the anterior cornua and degeneration of the anterior roots and peripheral nerves.

In myopathies the central nervous system as a rule is intact, but the muscular fasciculi are primarily undergoing atrophy, and the perifascicular connective tissue undergoes hypertrophic changes. Several members of the same family may be affected, but the morbid type varies from one family to another and presents intermediary subvarieties. In the latter the atrophy may commence in different localities. Atrophy may affect some muscles always in the beginning of the morbid process, others in the course of the disease, while still others remain almost in-



variably intact. There seems to be a relationship between the precocity of muscular development and their predisposition to myopathy. Curiously enough, one observes in some families only the male members affected and the disease is transmitted solely by the women who themselves have not presented muscular atrophy.

Atrophy is not the only muscular affection that disturbs locomotion. Myotonia, myoclonia, chorea, tremors are the other disorders which are sometimes seen in some members of the same family.

Thomsen's disease or familial myotonia, as is well known, is a disturbance of muscular function which consists of a sudden contraction of the muscles as soon as the patient makes a movement. The disorder is transitory, although it produces a temporary disability. The disorder is predominant in the lower extremities, although it may occur in the upper ones and in other muscles, tongue and eye included. The affection is conspicuously familial in character. Thomsen himself suffered from it and he describes eleven cases in his family. Females are apparently exempt from this affection. The muscular force is diminished in spite of the fact that the muscles are hypertrophied. However, the development of the muscular fibre is incomplete, it remains in a state similar to an embryonic state. Evidently we are dealing with a familial disorder, manifesting itself in a defective development of muscular tissue.

Among other forms of familial disordered locomotion may be mentioned various muscular twitchings and contractions. Chorea, myoclonia, tremor are affections which may be encountered in members of the same family. I have a record of three families in whom a large number of members presented at various ages and in two generations episodic attacks of Sydenham's chorea. In Huntington's disease which is a chronic form of chorea the hereditary and familial character is typical. Here the affection makes its appearance in the middle age of life affecting both sexes equally. It is progressive and terminates with an enfeeblement of the intellect and complete physical deterioration. The hereditary character is direct and in the cases recorded in the literature it never missed one generation.

Tremors as distinguished from choreic movements may also be present in several members of the same family. There are in existence socalled families of tremblers.

The morbid phenomenon commences at a certain age and increases as the individual advances. In Debove and Renaut's genealogical tree of one family both conjugal parties were tremblers. Almost all their descendants with very few exceptions were tremblers.

Spastic paralysis of the lower extremities with all the characteristic changes in the reflex action due to an atrophy of the pyramidal tracts has been observed first by Strümpell in several members of the same family. Since then quite a number of similar records have been reported, either in the pure form or in a form intermediate between this affection and the heredocerebellar ataxia. The disease usually appears between fifteen and thirty years of age. In one family that came under my observation there were seven members affected with spastic paraplegia: four of them began to show the spasticity at the age of three. Six of them were males and one a female. In families thus affected, there is usually present some degenerative basis; either insanities, neuroses or alcoholism, consanguinity, syphilis. In the above case one paternal uncle was a paranoiac and a sister of the mother died at the age of thirty in dementia precox. This type of the disease remains usually unchanged until the end of the patient's life, but sometimes, years after the onset, new symptoms develop and the picture of multiple sclerosis becomes apparent. In the family spastic paralysis we are dealing with a primary systemic degeneration of the pyramidal tract which is a result of a congenital malformation.

Oddo and Audibert in France have called attention to a curious affection which is characterized by a periodical or intermittent loss of power, in the extremities, mostly in the lower, and occurring in several members of the same family. The paralysis is sudden and occurs usually after a more or less prolonged period of muscular inactivity. It is flaccid in character and during the attack the affected muscles cannot contract on stimulation; electrical reactions are greatly diminished or totally abolished.

I had the opportunity of observing a family of four children, three of whom, all girls, and one uncle, brother of their father, suffered from intermittent attacks of complete loss of power in the limbs. The children's disability was confined to the arms, but the uncle's to the legs. Suddenly without warning and after an exertion they would be absolutely unable to move their limbs. The condition would last but two or three hours. During this period the tendon reflexes could not be obtained and the electrical contractility was much diminished to faradic and galvanic currents. Sensibility and intelligence were intact. In the intervals between the attacks the motility and muscular power were perfectly normal; the electrical contractility was normal and the reflexes were all present. In every other respect the four patients were in good health. The father of these children told me that frequently, but not regularly, for many minutes at the time, he also would suddenly lose power in the hands. A vigorous rub brings the hands to normal. This condition occurs to him in the midst of perfect health and without feeling fatigued in any other part of the body. He evidently presented a *forme fruste* of the same affection with which his children and his brother were afflicted.

Holtzapple reported a history of seventeen patients distributed over four generations of the same family, who presented symptoms of periodic paralysis. The affection probably is due to a congenital defect of the muscular tissue which under the influence of a physical effort is unable to contract to a degree sufficient to carry out the work assigned to it.

To sum up the present study of disorders of locomotion occurring in one family of one or several generations, we must admit that the subject is one of structural anomalies created by evolutional disturbances. They are variations from the architectural normal type. They create a predisposition which exists at the time of conception and is therefore transmitted to the product of the latter.

The knowledge of the laws of heredity and of the biological modifications which are the resultant of

pathological modifications of the creating organisms is of paramount value from the viewpoint of eugenics. Familial diseases or defects are governed by the general laws which are identical with those which regulate the transmission of normal morphological characteristics from the highest to the lowest point of the animal scale. Morbid heredity, as far as familial diseases are concerned, is controlled by the same laws as physiological heredity.

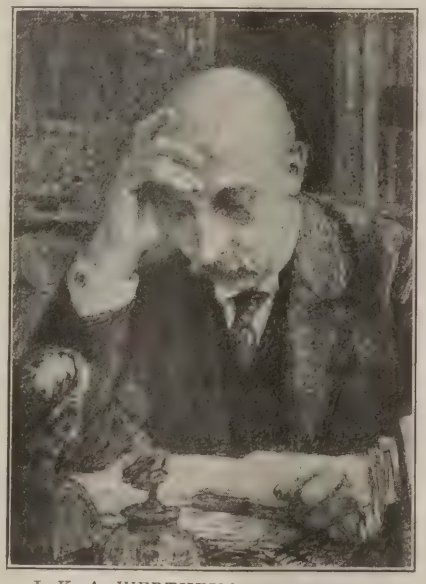
1812 Spruce Street.

Dutch Neuropsychiatry and Its Representatives*

SMITH ELY JELLIFFE, M.D.
New York

On this occasion, when this society welcomes as its new president Dr. E. G. Zabriskie, a worthy scion of one of the earliest Dutch families of our beloved New Amsterdam and Breukelin, it seems a happy coincidence that I should be able to turn your attention not to the achievements of what the split off new world descendants of those worthies of the seventeenth century have accomplished in the field of neuropsychiatry, but rather to point out even if but very fragmentarily, what they are now doing at home in Holland.

Even though my discussion must of necessity be but a touch and go, and though I can not show you to the full what the present day Dutch school of neuropsychiaters is accomplishing, it may be stated that for so small a group it probably presents the greatest number of eminent workers in this field today.



J. K. A. WERTHEIM SALOMONSON

It is in a measure to be regretted that we have not preserved a little more of that old Platt-Deutsch that first set its stamp on New Amsterdam, Brooklyn, Hoboken, Flatbush and many other names which reach our ears daily, else the work of these Dutch workers would be better known to us as they, for instance, have been recorded in the *Neurologisches en Psychiatrische Bladen,* now in its twenty-sixth year, as well as in several excellent Dutch medical journals. In the past ten years, however, Dutch investigators have used more French and German, and many record their observations in English even in their Dutch magazines.

Had I the space I should have liked to present in orderly review the development of Dutch neuropsychiatry. In this I could have culled from the work of a Miss Mesdag, who has recently prepared a full bibliography of Dutch neuropsychiatry, but I must forego this pleasure and take you directly into Holland and point out the few spots in the medical landscape that my time permits.

I must first regretfully call attention to the recent death of two of Holland's most genial workers, J. K. A. Wertheim Salomonson and C. A. Pekelharing.

On September 16, 1922, J. K. A. Wertheim Salomonson, rector of the University of Amsterdam, died suddenly of heart disease at the age of fifty-eight. This was a severe loss for science in Holland as well as in other countries, for his research work has been of great value.

Dr. Wertheim Salomonson worked very much in science, but he was not a dry scholar. He was a lover of art, had a great aptitude for music and was also a first rate sportsman. Alike in his person, in social intercourse, and at work, he maintained the appearance of an aristocrat. He trained many neurologists and all had a high opinion of him and admired his scientific methods.

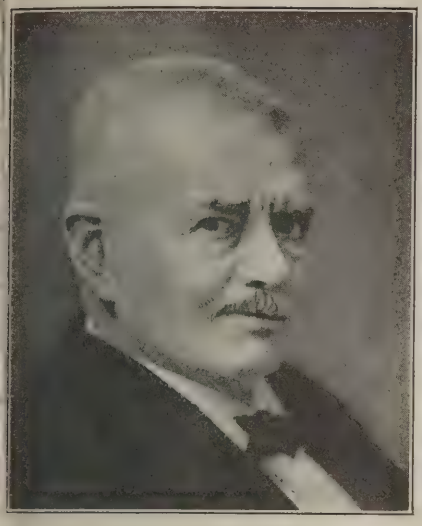
The work of Pekelharing, whose death also took place quite recently, was chiefly in biochemistry and I must needs pass him without further mention save as I may touch upon the problems of muscle tonus to which Pekelharing contributed many years ago.

The present dean of Dutch neuropsychiatry is Professor C. Winkler, for many years in Amsterdam in the university as professor of neurology and now for nine years professor of psychiatry, and director of the University Clinic at Utrecht.

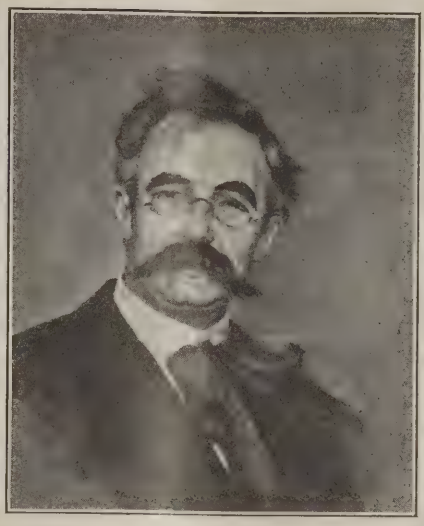
Winkler has a modern psychopathic hospital. Here for the past ten years he has done work which has been an inspiration to his fellow workers. They have shown their admiration of this work in gathering together now in eight volumes his *Opera Omnia.* These volumes are a mine of neurological lore. It is not without a certain amount of interest to look at Prof. C. A. Pekelharing's introduction written on the occasion of the presentation of these volumes, commemorative of the twenty-fifth anniversary of Winkler's professorship. They include practically all of his work, omitting only two atlases prepared in collaboration with Dr. Potter.

Winkler was born in 1855; his father and grandfather were physicians. He was a precocious boy. At eighteen he entered the University as a medical

*Illustrated Talk to New York Neurological Society, February 6, 1923.



C. WINKLER



LOUIS BOLK

S. DE BOER

student. He there became much intrigued by pathological anatomy under Talma and his graduate dissertation was upon tuberculosis. It was not a remarkable dissertation. At his graduation he entered the surgical service of a communal hospital at the Hague under an uncle. He soon left there for Utrecht to be an assistant to Talma and to devote his life to research. Here he very early turned to neuropathology and to neuropsychiatry.

It was in 1876 that special chairs in psychiatry were voted to be instituted in the Dutch universities by the Government, but they were dilatory in providing the necessary budgets. Schroeder von der Kolk was among the earlier teachers in this specialty. In 1885, having developed a fairly large private clientele, Winkler was appointed lecturer in psychiatry and then visited the newly established German Kliniks of Heidelberg, Gudden at Munich, and Meynert at Vienna. His opening address on Psychopathology in October, 1885, (*Opera Omnia,* Vol. 1, page 143) can be read at this time to advantage. His interest in the functions of the brain soon led him to devote much time to brain surgery in which direction he was in constant liaison with Guldenarm, the surgeon of the university, his two years' surgical service at the Hague having made him an excellent surgical assistant. He soon founded a polyclinic service in neurology and for the study of the neuroses and later gave courses in criminal anthropology to the law students.

All of this time the Government hesitated to supply funds and accommodations for a clinic along broad lines and he was constantly engaged in political propaganda to advance the cause of neuropsychiatry. Finally he resigned from his Utrecht lectureship because he could not get the politicians to move and finding better opportunities for psychiatric research in Amsterdam he was appointed in 1896 professor in that university. During nineteen years he advanced this work in Amsterdam, the rich results of which are collected in the volumes of which I have spoken. He attracted a large number of students, and also founded the neuropsychiatric society and by reason of his activities as a member of the Royal Academy of Sciences, he brought to fruition the foundation of a Central Institute for Brain Research. Dr. Ariëns Kappers, one of his pupils, and of whom we shall speak, was made its director. A Central Brain Commission was founded at this time. Some of you are acquainted with the marvellous

R. MAGNUS

A. DE KLEIJN

E. JELGERSMA

plates which this Commission, with the aid of the Royal Society have published. Von Monakow of Zürich is still one of its most active members. Its work has been seriously interfered with by the war.

In his psychiatric work, founded on exact anatomical knowledge, on physiological experimentation, his surgical training having made him an adept in this line, he did not neglect clinical observation. "Therapeutic results" was his constant aim, and the end of his researches was to benefit those with whom he came in direct contact. His laboratory researches were always guided by personal clinical problems. He was, as Pekelharing observes, a master in every aspect of his work. His observations were thorough, his diagnostic acumen keen, his research patient and profound and his therapeutic results striking. His was a remarkable catholicity of point of view and he always deprecated the narrower issues of founding a "school" which was so outstanding an attribute of the German universities.

In the meantime the Utrecht situation was advancing and finally by 1900 a chair of psychiatry was actually financed. Ziehen came from Jena and took charge in a modest way for only three years. Heilbronner was his successor, but not content with the meager provisions put up with by Ziehen, demanded a proper clinic in the modern sense. By 1907 the dilatory Government accepted but it took them until 1913 to finally complete the full plan. In September, 1914, in the trying days of the opening of the war, Heilbronner died suddenly of heart disease.

It was then that the authorities turned to Winkler. Now it was their time to worry. Utrecht had finally, 1914, achieved what thirty years previously Winkler had fought for. He finally, after much persuasion, agreed to take over the Clinic. His inaugural address was on the Relationship of Psychology to the Physiology of the Nervous System (*Opera Omnia,* Vol. 5, page 541). It was a summing up of three previous discourses, the study of which offers the most complete insight into Winkler's position at that time. The first, The Localization of Psychical Functions in the Central Nervous System (*Opera Omnia,* Vol. 5, page 63); the second On the Relative Value of Localization (*Opera Omnia,* Vol. 5, page 291) and the third The Structure of the Cerebral Cortex and New Facts in the Localization of Our Perceptions (*Opera Omnia,* Vol. 5, page 471).

Winkler here develops his major premises that anatomical, physiological and clinical research on the structure and function of diverse portions of the nervous system are essential. They are detailed requisites which, as Pekelharing remarks, many who would think of themselves as philosophers, are disposed to regard somewhat with disdain. But throughout it is clear that Winkler constantly is preoccupied with a most difficult problem—one of much importance, namely that of the soul and its relations to the body. In a strictly scientific manner, following his natural history bent, he has regularly explored this difficult territory constantly seeking to arrive at conceptions which would make matters comprehensible. Originally much taken with Wernicke's ideas in psychiatry his tendency to keep free from any of the limiting advocacies and controversies more or less due as a follower of a socalled school, led him more and more into broader biological formulations. He went, as it were, in and out of schools, an individualist and an originator.

Thus, as may be seen on the title page of his great *Manuel de Neurologie,* Vols. VI and VII of his Opera Omnia, he was an advocate of the energic hypothesis that the human body was a capturer, transformer and deliverer of energy. "An Effort at Grouping in Functional Systems, the Pathways and Centres of Diverse Localization, whereby diverse Sensory Impressions can be transformed into Reflex Activities." This is a program rigidly adhered to, so far as present day research will permit.

Much as I should like to present a résumé of his detailed researches, which cover an enormous field, space does not permit. I must content to stress some of his, to me, most fascinating suggestions concerning certain functional aspects of the auditory nerve. Inasmuch as we shall take up the work of some others in this regard, notably that of Magnus, Kleijn, the general situation may be glimpsed. After treating at great length and in detail the proprioceptive functions of the members and their biological functions in the nutritive complex, Winkler in his chapter on the eighth nerve, brings out that this group is both phylogenetically and ontogenetically a cutaneous one and that of all of the proprioceptive systems it is probably the oldest group. To grasp its history one must go back to the marine habitat in order to trace the results of adaptation to water shock with their consequent physical variations to pressure. The proprioceptive system he suggests was originally created here, since modifications in the water supply needed appropriate adjustment in the maintenance of the nutritive complex. Here, as undoubtedly for the tracing of the phylogeny of many other functions of vertebrate animals, one must go to the invertebrates.

The statocyst organ, advantageously studied in marine molluscs (Pterotrachea is the one chosen), is the beginning of this history. Two facts have been demonstrated regarding this organ: 1, Its sensorial cells can be affected by rhythmic vibrations by the intermediation of the otoliths; 2, It exercises an influence on the equilibrium (i. e. space adjustments) of the animal. Coelenterates and crustaceans possess this organ and Kreidl has shown a remarkable uniformity of function throughout an ascending series of invertebrates.

The displacements of the otoliths in the statocyst, as the origin of the regulation of very complicated movements in which the head, the trunk and the eyes are involved, has become, largely through the investigations of Breuer, a valuable point of departure for the functional study of the labyrinth. It is striking that the first development of a central nervous system should arise with the appearance of the statocyst and the eye, and there flows from this, says Winkler, the conclusion that the labyrinth is the most ancient of the sensory organs. Moreover, the fundamental organization of the statocyst maintains itself in all of the animal series even through the superior vertebrates, in which those modifications in the form of the organ arise which have come to be termed the labyrinth. We shall not trace the gradual modifications in their development, these have been done with great acuity by

Schepman, also a Dutch naturalist, but arrive at the elaboration of an octavolateral system which is to be considered as an ensemble. In this are to be distinguished, the vestibular and cochlear nerve components. The organ of Corti is representative as the receptor of the cochlear component, gradually elaborated as the stimuli took on more and more of a terrestrial character, and what we designate as sound wave components, were added to those of a more aquatic nature. Notwithstanding the fact that the two elements of the octavolateral system seemed quite different, careful research shows an essential unity. Whereas it has been assumed that the two functions for higher vertebrates termed "spatial adjustment" and "hearing," have developed separately and were by accident more or less united, a view to which Jelliffe and White gave assent in the first three editions of their *Diseases of the Nervous System,* we are convinced on going over the evidence presented by Winkler and those quoted by him that this is incorrect, and adopt the view in our new fourth edition (1923) that the hearing function has gradually evolved out of the primitive water shock mechanism of the statocyst, to respond more and more to air shock reflex activities.

Thus bodily displacement has come under the reflex response of two types of stimuli originally one, but gradually separated. The cochlea has come to represent an organ originally reacting to a different type of water shock, but more and more to air borne stimuli, audition, and has resulted in intermittent tonic muscular reactions, rhythmic movement reflexes such as swaying, the dance, singing and finally speech reactive activities. The recital of the barest outline of the details of this gradually developing synthesis either from standpoints of structure or function would consume many hours. I leave it to your individual reasoning capacities to grasp how the intermittent reflex activities through the larynx, the tongue and the muscles of the lips have acquired their special importance. *"Because, above all they conserve as a heritage of ancient function, the remarkable and particular faculty of all the static organs, namely to reproduce by reflex pathways the phenomena which have given rise to the stimulus."* When a shock of water acts upon the body with a certain force, the statocyst determines a displacement of the body of similar importance (adaptation). In the same manner for the shocks which come through the air. The sensory organ (Corti) excited by sound vibrations, is capable of reproducing the same vibrations by the organs which it commands. This is a characteristic function of the acoustic apparatus, to determine by integrated reflex pathways, in the phonation mechanism, also widespread in the body musculature, vegetative, and this must be emphasized, as well as sensorimotor, intermittent contractions, in that it reproduces a sound (or a movement) identical to that which has been the point of departure of the excitation. The sound stimulus is thus reproduced as a rhythmic wave by the phonating mechanism of the animal that perceives it. It is but a corollary that the acoustic mechanism has developed more and more a unique mode of response. In the simpler sensory organs the initial stimulus is responded to directly, whereas for the intermittent stimuli which have become more and more complex, a constant tonic apparatus, as a foundation, is essential. Thus has language been developed and with this human intelligence. Here the reflex responses have become highly subtle and complicated, but still governed by the same fundamental laws. The organ of Corti has come to represent the complex receptor apparatus in the zones of language, its telencephalization—as the cortical integration mechanisms. (See pages 155, 156, Vol. II, Winkler: *Manuel de Neurologie.*)

Institute for Brain Investigation, at Amsterdam; Dr. C. V. Ariëns Kappers, director.

In the mammalian octavolateral system (labyrinthine complex) there are to be distinguished at least four neuroepithelial structures: a, the striæ nervosæ in the semicircular canals; b, the maculæ, or taches sensorielles of the utricle and saccule; c, the tristæ, or cretes sensorielles, of the ampoules; d, organ of Corti, in the cochlea. The most recent of these is the organ of Corti, which reaches its complete development only in the mammalia. The cretes sensorielles of the ampoules are older; the oldest of all the structures are those of the maculæ.

Winkler, following Magnus and de Kleijn, compares the maculæ to the primitive statocyst of invertebrates. These organs primarily function for the maintenance of general muscular tonus. They collaborate with the proprioceptive stimuli from the body. The function of the cretes sensorielles of the ampoules is of later evolution, and is more specialized. They have appeared for the registration of the movements of the head and for the head organs, chiefly the eye movements. They remain in close liaison with the general tonus functions of the maculæ. *These regulatory functions are strictly condensations of geotropic reflex activities and are purely unconscious.* Rhythmic activities have not yet taken on their social rôle. These are still to develop as various forms of more conscious bodily displacement, marching, dancing, unison actions, and other movements, chiefly initiated through sound waves, and closely related with the development of laryngeal and buccal proprioceptive stimuli asso-

ciated with the developing speech function. Thus the organ of Corti has come to be developed in response to a wider conscious acquisition of control of bodily movement, including tongue movements, i. e., speech, in its social orientation function. These reflexes for bodily orientation are no longer geotropic and entirely unconscious, they are taking on sociotropic activities, partly conscious, and in the highest cultural types becoming consciously socially valuable. The organ of Corti then is functioning in response to rhythmic or interrupted stimuli from the bodily organs and from the tongue through its symbol formations. How Winkler further develops his argument must be left to the reader, who will be well repaid to go carefully over the details (p. 127).

Nowhere has the reviewer found so sound or penetrating a view of the development of the affective response to sound stimuli through muscular displacement and imitation. What the newer psychopathology is finding out with reference to unconscious social reactions to tone, to voice, etc., is well worked out by Winkler in his analysis of the unconscious reflex awakening of sonorous response to motor stimulus. Thus is laid down a true physiology of affective effector release from the sound—and vision—of muscular stimuli in the environment. We thus see how extremely valuable language has become as a type of stimulus as well as release mechanism through gradual condensation of language symbols. Thereby the body and its organs are not required to go through severe and dangerous displacements if through language the necessary socially valuable protective stimulus and discharge can be found. I have presented to this society from time to time the definite corollary of this in speaking of the affective discharge value of the symbol, particularly in its relation to a dynamic pathology in chronic disease of various types, and this complete analysis of the pathways through which and by means of which this is made possible is of much interest. The whole psychopathological argument relative to human response to emotional stimuli is brought nearer to structural facts in this masterly chapter on the eighth nerve.

Muscle tonus.—During the past ten years the subject of muscle tonus has been actively discussed by a number of workers of the Holland school. This cannot be expounded exhaustively and I regret that my collection of portraits is still incomplete. Among the workers whose contributions to the subject have entitled them to world wide recognition and discussion are De Boer, Boeke, Dusser de Barenne, so far as the sympathetic participation in motor innervation is concerned, and the work of van Rijnberk, Winkler, Jelgersma, Magnus and Kleijn and Brouwer.

Concerning the socalled double motor innervation of striped muscle tissue even the Dutch workers are at considerable loggerheads. No attempt will be made here to conciliate the various views nor to present a complete historical resumé. There are plenty of these in the literature. It may be recalled that Langelaans (1), Brondgeest, Pekelharing and his pupils, Hoogenhuijze, Verploegh and Harkink whose names are bound up in the discoveries, were all among the earlier workers of this problem.

J. G. Boeke (2), anatomist at Utrecht as early as 1909, by means of Bielschowsky preparations showed small neurofibrillar end rings, and end nets, at the end of fine nonmedullated nerve fibres. These were quite distinct from the ordinary end plates well known as constituting effector muscle organs of the pyramidal system. These socalled accessory nerve endings lie hypolemmally on the muscle fibers embedded in the granular sarcoplasm of the fiber. Boeke believe these to be of vegetative nature. These sympathetic fibers were found by many others and their presence as structures may be said to be fairly well established.

Whereas the morphological problem (3) may be said to be fairly well established the physiological one is actively discussed here. De Boer's studies may be of interest since he has been one of the most active of this group in claiming the plastic tonus function of these vegetative effector mechanisms. With the study of their pathways to the cord and their higher synaptic junctions in the striatum of our own Ramsay Hunt, we are somewhat, though not securely, acquainted. Concerning the peripheral activities the Dutch observers have apparently separated mechanical from chemical vegetative functions and the chief discussions focus as to the respective merits of plastic mechanical factors, and chemical nutritive factors, in the study of which latter Pekelharing and his pupils and Dusser de Barenne have made some interesting observations.

The analysis of the plastic tonus mechanism is one of much complexity—some of the notions of de Boers, privat dozent of physiology in the University of Amsterdam, may be alluded to (4). Following a clue given by some work by Meyer and Weiler (1916) by H. Fröhlich, and H. H. Meyer, Liljestrand and Magnus and others, that isolated muscular cramps due to tetanus can be completely inhibited by intramuscular injections of novocaine without any loss in the usual sensorimotor functions of the muscles, DeBoer repeats the experiments and brings them in liaison with the earlier ones of Brondgeest, who obtained loss of plastic tonus by section of the posterior roots, and of his own and of Dusser de Barenne by section of the rami communicantes. These results all converge to afford much foundation for the hypothesis that a vegetative factor of plastic tonus is to be found in the effector nerve nets of Boeke and that this type of tonus is under sympathetic control. De Boer has attempted to disprove Liljestrand's and Magnus's position that novocaine poisoned the muscle proprioceptors, and also Dusser de Barenne's opinions that the tonus reflex arc is conducted through the motor cerebrospinal pathways. He shows that sodium sulphocyanate can bring about the tetanus-like reactions herein referred to and they can be entirely abrogated through the concomitant action of novocaine.

These, his latest experiments along lines of pharmacological dynamisms, coupled with his earlier ones (veratrine and electromyogram studies) enable him to come to a fairly definite conclusion that skeletal muscle tonus has a definite peripheral autonomic reflex are component (5).

I need not point out the numerous correlates that

low from such a conception, and what a flood of xperimental possibilities pour from them, particularly in the numerous perplexing muscle syndromes ne meets with in encephalitis, in catatonia, in tics, n the psychoneuroses, etc. Dr. Dana in a personal ommunication thus speaks of a marked increase in asal metabolism in one of his postencephalitic arkinsonian patients. This might well be studied rom the point of view of Pekelharing's researches n protein (creatinine) metabolism and the tonus echanism of striped muscle. Dusser de Barenne n support of his position while admitting that the ibres and accessory en dplates of Boeke are vegeative in origin does not believe, however, that they ave anything to do with mechanical, i. e., Brondeest tonus. These are due to the motor nerve fibres. hemical muscle tonus is their function. How this perates is still a mystery (7). Dusser de Barenne's 8) work on sensory localizations in the cerebral ortex, I can mention only, and also only touch upon is contribution to other relationships studied beween the sympathetics and muscle tone. Thus decerebrate rigidity does not seem to be modified when he muscles are deprived of their sympathetic reflex rcs.

These studies lead us into the most complex of eurological problems, especially as we try to trace he upper coordinates of these tonic mechanisms. hese open up into a wilderness of clinical observaions and experimental researches in the solution f which the entire neurological world is engaged. ince Sherrington published his volume on integraion actions of the nervous system, the Vogts their ork on the striatum, Wilson his observations on he lenticular nucleus, no problem has been more ctively discussed than the subject of muscle tonus nd its higher synaptic controls.

I purpose calling your attention here solely to he work of two or three of the Dutch workers with hese problems. Chiefly Van Rijnberk, whose reearches on the cerebellum have been alluded to, and o Magnus and Kleijn. I regret I must be so curory.

In 1915 Van Rijnberk on the basis of the newly cquired notions concerning the double motor inervation of voluntary muscles, subjected the paraoxical lingual phenomena of Vulpian to a reanalyis. This was made a contribution to the study of nuscular tonus and its innervation (9).

Until Boeke had in 1913 made it fairly certain hat there was a vegetative supply to striped muscle he older hypothesis to account for Vulpian's linual paradox remained inadequate. By the aid of hese newer views Van Rijnberk sought to clarify he situation. It is not impossible that the muscular onic phenomena following facial palsies are of this ature. Pursuing the question further Van Rijnerk subjected certain observations of Sherrington n the "foot phenomena" to further investigation nd found they fell in the same category. He then 1917) advanced to the study of muscle tonus in ecerebrate rigidity and entered the illimitable field f the significance of muscle tonus as a determiner f postural reactions, a field which as you know Engish physiology has cultivated with special persistnce and good fortune.

I must leave Van Rijnberk at this point and consider for a moment some of the work of Magnus and Kleijn whose masterly researches have concerned themselves with certain aspects of this same problem. Magnus and Kleijn are pharmacologists in the University of Utrecht. One could spend several evenings, in discussing the work of the past ten years by these investigators. Following up Sherrington's Studies in Decerebrate Rigidity they showed that the phenomena were partly related to synaptic stations lying in the brain stem, caudad to the plane of the anterior corpora quadrigemina and cephalad of the plane of the calamus scriptorius. The cerebellum seems to play no essential part in this postural reflex syndrome. This "standing decerebrate animal" as naturally one might suppose, was not a simple automaton, however, and Magnus and Kleijn in decomposing some of the elements in the syndrome first made clear that labyrinthine and neck reflexes could be separated. The *tonic labyrinth reflexes* arose from stimulation of the otoliths. The *tonic neck reflexes* arise in the proprioceptive nerve endings of the cervical muscles. Further analysis of labyrinthine components showed that each labyrinth influences the tonus of the limb muscles of both sides equally, the trunk and eye muscles bilaterally but chiefly contralateral, the neck muscles of one side, contralaterally Magnus went on to analyze the socalled thalamus and midbrain animals by extending the transections caudad of the calamus scriptorius. The syndromes arising have common tonus factors, but different metabolic reactions. Temperature variation is one reaction affected. Magnus is analyzing this complex problem of the neural pathways of temperature regulations. While at St. Moritz, where I saw him in 1921, he was studying certain peripheral processes set up by stimuli of the gases in the waters there. The tonus is "normal." The "postural reflexes" (Stell reflexe) of Magnus are contrasted with the tonic reactions of the decerebrate animal (Steh reflexe).

In the postural reflex four components have been described. 1. Head labyrinthine reflexes. 2. Body wall reflexes influencing head positions. 3. Neck muscle reflexes, combined with, 4. Trunk and limb muscle reflexes.

Two of these handle the position of the head in space, two that of body displacement. Magnus and Kleijn have very ingeniously analyzed the reactions to gravity and pressure stimuli in their socalled *Brettversuch.*

As one rises in the phyletic series, in monkeys for instance, eye muscle reflex participations in the stellreflexe are striking. I can not in my short time go further (10). Most of the work here referred to has appeared in *Pflüger's Archiv.* A later paper, Magnus: Körperstellung and Labyrinth Reflexe beim Affen. *Pflüger's Arch.* 193, 1922, 396, is not included in Walshe's review. (A. de Kleijn and A. de Kleyn, both spellings used by author.)

The Cerebellum. I have no intention at this time, or indeed at any time, to attempt a presentation of the subject of the cerebellum. This can be found elsewhere (11). I shall speak only of some living Dutch neuropsychiaters who have made most important contributions to our knowledge of cerebellar

morphology and physiology. As already intimated, in this small group of men, the researches of all have crossed each others' trail, so that it is quite impossible to isolate the researches. Thus Brouwer's valuable work on the Olives as Part of the Cerebellar Components would with reason come within the frame of these paragraphs. But I shall first briefly mention the work of one of the great innovators in cerebellar physiology: Bolk. The name of that illustrious English anatomist, Elliot Smith, is closely linked with that of Bolk. His was, in a sense, the stimulus which determined a break on the part of both from older views concerning cerebellar structure. Previously to the newer views of Smith and Bolk the cerebellum had been studied chiefly, as it were, from above down, whereas with Bolk's schematizations, the comparative anatomy method, from below up, came to its most satisfactory expression. Smith worked primarily with Edentates, Bolk with Lemur albifrons and their work has now been fairly well recognized as fundamental. On the physiological side Van Rijnberk, professor of physiology in Amsterdam, has made many important studies. Many of his researches as well as those of numerous others of the Dutch school are found in the *Folia Neurobiologica,* a journal started by Ariëns Kappers which unfortunately has had to cease publication for a time.

What Bolk really contributed can only be glimpsed here and I can do no better than to borrow somewhat from Tilney's masterly summary of the Evolutionary Significance of the Cerebellum: "Bolk, as the result of a study of the cerebellum in a large comparative series, still further advanced the ideas put forward by Elliot Smith. He concluded that the several parts recognizable in the mammalian cerebellum have definite functional significance and represent areas of central control over definite motor performances in the body.

(*To be concluded*)

The Principles of Reeducation of the Muscles in the Treatment of Hemiplegics

P. KOUINDJY, M.D.,
Paris, France

Nearly twenty-four years ago I called attention for the first time to the encouraging results to be obtained from motor reeducation in the treatment of hemiplegic patients. At the International Medical Congress of 1900 (1), and in the *Archives de neurologie* (2) of the same year, I emphasized the need of ascertaining, above all, the amount of motion which the hemiplegic case is capable of carrying out, and which should be patiently sought, even if present only as a minor residuum. Since that time I have had the opportunity of caring for many hemiplegics, both in the Charcot Clinic at the Saltpêtrière, in my private practice and at the Val-de-Grâce. I feel justified in asserting that, whatever may have been the origin of the hemiplegia, these patients retain in varying degrees the power of motion in their paralyzed muscular apparatus. Such motion is more or less appreciable according to the state of paralysis and the period of time the disturbance has existed. In a general way, indeed, muscular hypotonicity, atony and atrophy do not involve all the muscles at once. The topography of the muscular atrophy in hemiplegics varies in different patients, and frequently, in the same patient, at different stages of the condition. Wernicke (3), Mann (4), and Clavey (5) attempted to lay down a definite topography of the muscular hypotonicity of hemiplegics. Their topographical conclusions are far from perfect, yet show that in the majority of cases hypotonicity (atony and atrophy) involves approximately the same muscles. Thus, in the lower extremities the muscles very extensively involved are as follows: iliopsoas, tensor fascia, femoris, sartorius, quadriceps, peronei, flexors of the foot, extensor brevis digitorum and interossei. Those partly involved are: The glutei, the gracilis and the tibialis anticus. In the upper extremities, the muscles most seriously involved are: The supraspinatus and infraspinatus, subscapularis, middle portion of the trapezius, serratus magnus, deltoid, triceps, supinator longus, supinator brevis, radiales muscles, opponens pollicis, long extensors of the fingers, interossei and abductor brevis pollices. These conditions may, as already stated, vary from one case to the next; for, according to the opinion of my chief, Professor Déjérine, "In a hemiplegic all the muscles participate more or less in the paralysis."

Again, these topographical conditions depend likewise on the contracture of the antagonists. This contracture, which is very common in residual hemiplegia, sometimes follows rather quickly upon flaccid hemiplegia; Gilles de la Tourette found it in seventeen out of twenty cases (6), and Schafer in sixty per cent. of cases (7). According to Brissaud and Souques, it is almost constant (8). In my opinion, contracture sets in in the hemiplegic already at the beginning of the disorder; it is more or less pronounced, according to the state of hypotonicity of the affected muscles, but if one knows how to detect it, it is never wanting. It is this contracture which often misleads when the observer thinks he has found motility in the paralyzed member. Upon carefully examining the motility of an extremity or portion of an extremity in the hemiplegic case, one ultimately discovers that the motion produced occurs principally in the contractured muscles and that the predominant activity of these muscles often results in motor impotence, the muscles in a state of contracture completely overbalancing the function of those which are in a state of hypotonicity. Accord-

ngly, it is necessary in muscle training so to select he exercises that their effects shall be concentrated pon the hypotonic muscles, in spite of the contracture. These exercises should have for their purpose he procuring of easy and regular locomotion for the patient, as well as the ability to make use of his rm.

In the case of the lower extremities, the initial reducative exercises are intended to activate the unction of the flexors and extensors of the thigh n relation to the pelvis and the movements of the eg on the thigh and of the foot on the leg. These xercises, which are repeated two or three times a lay, consist of simple movements carried out in four tages, viz., 1, flexion of the thigh on the pelvis; 2, xtension of the leg on the thigh; 3, flexion of the leg n the thigh, and 4, placing of the foot on the ground, vith flexion of the foot on the leg. The exercises hould be carried out in the recumbent, sitting, and tanding postures. Apart from these exercises, the hysician should teach the patient to sit up in bed, nove to the edge of the bed, sit on the edge of the ed, and get out of bed. In the last mentioned exerise the patient should support himself either on the rm of an assistant, on a chair, or on a cane or stick. He should also be shown how to get onto the bed, o sit on its edge, and to get into the bed without utside assistance.

Equilibration exercises are next proceeded with, vith the aid of stools or footstools of varying height; eld by an assistant and later supporting himself o a cane, the patient must learn to place the foot of the ound side on these various stools and remain thus a few seconds or even minutes without support. Then, he must learn to get up onto a platform wenty-five to thirty centimetres high and to descend rom it, in the following way: To get onto the platform he must place on it first the foot of the sound ide, next his cane, and lastly the foot of the affected ide; to descend from it, he places on the floor first he affected foot, next the cane, and finally the sound oot. In the case of a leftsided hemiplegia, the foregoing directions may be summarized thus: To get p, right foot, cane and left foot; to get down, left oot, cane and right foot.

To teach my hemiplegics to walk, I make use of he procedure which consists in exaggerating the lexion of the thigh on the pelvis and in placing one foot in front of the other—a procedure opposite to hat of Erben (9), in which the patient always puts forward the sound limb. These exercises restore he activity of the flexors of the lower extremities during motion and permit of the avoidance of circumduction of the limb. When these exercises are egun, the patient has to be given support on the paralyzed side; then, when it is seen that he is able to carry them out by himself, the cane is used as support, being held by the hand of the sound side. This arrangement allows him to walk with a triangular basis of support, the feet occupying two angles of the triangle and the cane, the third. The act of walking is carried out in three phases: 1, Carrying of the affected foot forward; 2, placing of the cane at a point opposite this foot, and 3, carrying of the sound foot in front of the affected foot. As soon as the patient is seen to be able to balance his body on his legs, the act of walking is reduced to two stages: 1, Carrying of the affected foot and the cane forward; 2, carrying of the sound foot forward. The patient always starts with the affected foot, taking care to flex the legs on the pelvis as strongly as possible. The placing of the feet on the ground should be carried out with complete extension of the leg on the thigh; this is the only way for the patient to learn to walk without swinging his leg out laterally.

Certain rules must be followed in the process of training hemiplegics to walk. In the first place, care must be taken that the hemiplegic patient shall never fall down, as such a fall will engender in him a fear of walking and greatly retard his progress. Next, there should be no haste in getting him to walk alone, unless one is certain that the balance of his body on his legs is almost perfect. Again, a tendency on his part to plunge into walking at any cost must be curbed, for there is danger that he will not properly flex his legs on his pelvis and will consequently fall into the habit of throwing his limb out at the side in locomotion. He must not be allowed to walk bent over nor by dint of marked exertion. He must, in addition, be taught to place the affected foot on the floor in abduction and to ground his heel in doing so. This last desideratum is obtainable with persistence and permits of antagonizing effectually the contracture of the posterior muscles of the leg.

Reeducation of the process of locomotion in hemiplegics is not complete until they have been taught how to go up and down stairs. In either instance the mode of procedure is the same. To walk up an incline, the patient first puts his sound foot forward, then places the cane on a level with this foot and carries the affected foot near to the sound foot; to descend the incline, he puts his affected foot forward, likewise his cane, and then brings his sound foot toward the affected foot. In going up stairs, he first places his sound foot on the next higher step and then brings his cane and his affected foot onto the step on which the sound foot has already been placed. In all these exercises the sound leg is alone capable, especially at the beginning of the exercise, of keping the body balanced while in a state of semiflexion.

In hemiplegics I also make use of walking exercises carried out with the horizontal ladder I introduced for the functional reeducation of the war wounded. This ladder, made from three long beams five centimetres high, is divided by short crosspieces, likewise five centimetres high, into a number of compartments each thirty-five centimetres long and twenty-five centimetres wide. These compartments are so arranged that the compartments of one series alternate with those of the adjoining series. The crosspieces are removable and can be replaced by board partitions ten, fifteen, twenty and twenty-five centimetres high. In placing his feet in the compartments of each series the patient is compelled, in order to transfer his sound foot into the next compartment, to stiffen his affected leg, balance his body on this leg and see to it that this state of balance continues as long as the sound foot is not in position in the compartment. Again, in transferring the affected foot into the next compartment, he is compelled to flex the thigh on the pelvis and the leg on the thigh as completely as possible and to lift

up the foot as high as possible; otherwise, the affected foot may be stopped by the board and the exercise not be carried out properly. Furthermore, in order to place the affected foot properly in the next compartment without losing his balance, he is obliged to stretch the leg against the thigh as much as he can. Finally, if the exercise is to be executed correctly, the patient is compelled to keep his back perfectly straight. In all these exercises the hemiplegic patient trains his flexors and extensors and the muscles of his back.

Training the hemiplegic to walking out of doors is carried out by stages. The first time, he is called upon to cover a distance of five hundred metres. Then the distance is increased each day by fifty or one hundred metres, until he is able to cover satisfactorily one or two kilometres at a stretch. Care is taken to have him rest a sufficient time to enable him to undertake the return journey. Undue fatigue is to be avoided. These walks should be carried out once daily in the city, or at least twice daily in the country. A stay in the country is of great benefit to these patients and enables them rapidly to regain their morale and the major part of their muscular function.

Reeducation of the muscles of the upper extremities in hemiplegics is more difficult of execution. There are two main reasons for this: In the first place, the hemiplegic patient develops a more persistent will to learn to walk than to overcome the lack of power in his arm. Again, the considerable number of small muscles, having to do with the most delicate kinds of movements, which are involved in the paralysis, regain their power more slowly and call for greater patience and perseverance than are required in learning to walk. Indeed, nature herself contributes to a great extent in encouraging this form of negligence on the part of the hemiplegic, since, like many amputation cases, he ultimately gets accustomed to meeting his needs with but one arm. None the less, training of the muscles of the upper extremity permits of securing in many cases, if not a complete recovery, at least a very marked improvement in all movements.

When one has succeeded in overcoming, even partially, the arthritis of the scapulohumeral joint and the consequent ankylosis, training of the muscles appertaining to this joint should be proceeded with. The patient should be taught how to abduct his arm from his body and to move it forward and backward, at first while holding up his forearm in order to relieve it of its weight, then while resting the affected hand, even if closed, on the hand of the trainer held at varying elevations. Correct execution of movements should not be aimed at from the start in the process of reeducation. Later, when movements of elevation of the arm anteriorly, laterally and posteriorly are easily carried out, one should endeavor to correct the execution of these movements. In the meantime, the patient should be trained to place his hand over his head, on the back of his neck, on the opposite shoulder, on the different components of a piece of lattice work, on the back of a chair, on the table, on the walls, etc.

In obtaining extension of the forearm I have the patient proceed both in the recumbent, sitting and standing positions. In these three postures the patient is made to train himself to extend the forearm from the arm without jerking, steadily, and, as much as possible, at command. At first, use is made of small dumbbells, which, by their weight, assist in extension; then, the patient is required to go through the exercise without any assistance. When this result has been obtained, exercising of the fingers is proceeded with. Herein the sagacity of the reeducator must match his patience and perseverance. How many of our colleagues—and not the least of them—have been unduly severe to hemiplegics in their disheartening prognoses when, seeing the arm and hand in a condition of contracture, they have told them that nothing more can be done! How many hemiplegics have sacrificed their upper limb in following such deplorable advice. This sacrifice of the upper limb of hemiplegics has occurred simply because many practitioners have been and are still unaware that reeducation of the muscles, patiently applied, can ultimately master, if not completely, at least partly, this contractured condition of the hands of hemiplegics.

To demonstrate the fact that the prognoses referred to are often more than moderately prejudicial, I take the liberty of reproducing for my readers the personal case record of a colleague and friend of mine, suffering from leftsided hemiplegia, whom I treated by systematic massage and muscular reeducation. This personal record is reproduced with the consent of its author, who, as a professional man, was able to appreciate the inner significance of the training exercises and who applied them with the greatest benefit. It must be confessed that cooperation on the part of the patient contributes much toward the attainment of the object of the exercises, and that such cooperation is not always readily secured. Such was far from being the case, however, with my friend, an eminent physician and widely known practitioner, who manifested a desire himself to describe the manner in which he assisted my efforts to obtain recovery. I shall now let him speak himself, and am convinced from the start that the reader will appreciate the reproduction *in extenso* of this interesting personal record.

PERSONAL CASE RECORD OF DR. X

"Onset of the disorder, December 27, 1921. Progressive leftsided hemiplegia following a stroke, without loss of consciousness. In the morning, in my room, upon completing my morning toilet, I felt dizzy; I lay down and noticed that the limbs on my left side no longer responded to my will; the dizziness having passed off, the power of motion returned. Several times during the morning there was a feeling of dizziness with hemiplegia, followed by return of motor power; in the afternoon, however, the hemiplegia was definitely established and the dizziness disappeared. No headache nor premonitory symptom had caused me anxiety on the preceding days. The day before, I had walked as usual. I recollected merely that for some weeks I had felt a kind of tension and pulsation, without pain, which I referred to the right petrous region, but which had been present only intermittently.

"The established leftsided hemiplegia was complete, at first flaccid, but quickly followed by contracture of the flexors of the fingers and toes, exag-

gerated reflexes and atrophy of the muscle groups in a state of hypotonicity (triceps, extensors of the fingers, quadriceps extensor, extensors of the toes and lateral peronei). No subjective symptoms on the succeeding days; appetite retained; likewise, sleep, after insomnia for the first few days mainly on account of worry.

"I remained in bed, then in my room, for a month, swinging my leg out in walking. I saw Dr. Kouindjy the first time on February 15, 1922, a month and a half after the onset, and placed myself in his care for séances of massage and reeducation, which were carried out three times a week. Upon examination, Dr. Kouindjy made note of the muscles with lowered tonicity, chiefly the triceps, extensors of the fingers, quadriceps extensor, peronei and extensors of the toes, i. e., the antagonists of the contractured muscles. He endeavored to strengthen the hypotonic muscles by the different forms of massage, by hot air and by the active movements comprised in the procedure of reeducation. I must add that, even before seeing Dr. Kouindjy, I exercised the stronger muscles, such as the biceps and the flexors of the fingers, and that I was already satisfied with my ability to lift a chair with these muscles; but I very soon recognized the danger of the course I was following: I was strengthening the muscles in a state of hypertonicity and increasing their contracture. At the instance of Dr. Kouindjy, on the other hand, I worked at the extension of the forearm from the arm and at extension of the fingers, lifting with the extensors a weight attached by a cord to the extremity of the fingers; the weight was progressively increased.

"I also exercised in order to strengthen the power of supination. Thus, gradually the extension of the fingers and the supination succeeded in overcoming the contracture in flexion and pronation of the fingers and forearm. Similar steps were taken to master the contracture of the biceps.

"In the lower extremity, massage and reeducation were instituted with the same object, viz., to strengthen the hypotonic muscles in order to overcome the contracture of the hypertonic muscles—the latter consisting of the flexors of the leg on the thigh, the flexors of the toes and the tibialis anticus. Instead of extending the foot, a form of motion which came back rapidly, I labored, on the contrary, to flex the foot on the leg, and brought the heel in contact with the floor. I also practised extension of the leg on the thigh and abduction of the anterior end of the foot (lateral peronei), and not adduction (tibialis anticus).

"In practising all these movements, including those of the shoulder, I made use of various forms of apparatus. Thus, I admit that massage and reeducation can be administered only by some one specializing in this line of treatment and not by any untrained person. Reeducation, however, does not aim solely at the restoration of movements, but also at the performance of motor acts. A motor act is a combination of simultaneous and successive movements. Thus, the act of inserting the hand into the trouser pocket calls for several movements: Flexion of the forearm on the arm, carrying the elbow backward, throwing the coat back with the flexed fingers, extending the hand on the forearm, extending the fingers, then extending the forearm in order to cause the hand and extended fingers to enter the pocket. As long as my extensors were inferior in power to the flexors, I was unable to insert my hand in my trouser pocket, as this cannot be done with fingers flexed. I succeeded in doing this only three months after the onset of the disease (about April 1st). Putting the hand in the vest pocket is more difficult, as it calls for greater extension of the hand, with the elbow farther back.

"Similarly, the act of rolling a cigarette calls for successive flexion and extension of the forefinger while the thumb executes contrary movements. A motor act once accomplished, however imperfectly, can always be repeated. Rapidity of movement comes with habit, muscular power and flexibility. Accordingly, I endeavored to do as many things as possible with my left hand while eating, dressing, etc., and very often, in seeing little children play at country fairs, I compared myself with them in their manner of executing movements.

"Thus, following are the stages through which I passed in the process of recovery:

"In the beginning of March, 1922, I succeeded in rolling cigarettes, dressing and undressing without assistance; at the end of March, I could put my hand in my trousers pocket, and during April, that is, the fourth month after the onset of the disorder, I could drink from a glass and fill the glass from a decanter with my left hand. Locomotion was restored almost to normal, even without a cane, and likewise the climbing of stairs at first, then the descent of stairs —more difficult. Then, I trained myself to move the fingers separately, to extend them, to oppose the thumb and the other fingers—including, lastly, the little finger—in order to restore their flexibility.

"From the point of view of professional activities, the successive steps toward recovery were these: From the fourth month on, I was able readily to carry out percussion and palpation—two important means of examination for the physician, which call for complete extension of the fingers and hand. Then, I was able to administer hypodermic injections, general anesthesia with Ombrédanne's device, and apply dressings with firm pressure of the bandages. Finally, on May 30th, exactly five months after the onset of the disease, I personally assisted one of my friends in an operation for appendicitis.

"Such is the account of my case and of the valuable results obtained from reeducation of the muscles and systematic massage."

CONCLUSION

There is nothing to add to the personal case record of my friend, who presents a sufficient explanation of the principles underlying the application of the reeducating exercises used in the treatment of the upper extremity in hemiplegics. These exercises are intended in particular to reeducate the muscles in a state of lowered tonicity, which are the seat of a more or less advanced process of atrophy, according to the degree of paralysis and the length of time the condition has existed. With the assistance of the patient's will power and intelligence, the condition is ultimately conquered; it is merely necessary not to discourage him and condemn his arm to immobility from the start.

32 RUE DE LIÉGE.

Thromboangiitis Obliterans

BENJAMIN JABLONS, M.D.
New York

THEORIES OF CAUSATION

Thromboangiitis obliterans is one form of peripheral vascular disease which has attracted considerable attention in the past decade, and which seems to be increasing in importance as its diagnostic symptoms become better known. Since 1856, when Charcot (1) first called attention to this disease in men, although previously described by Bouley (2) in a horse, an extensive bibliography has arisen. For a time the condition known as thromboangiitis obliterans was confused with other conditions which it simulated in one or another regard. It is this seeming relationship which has created an extensive bibliography as well as a multitude of names. To cite some of the names which have been used indiscriminately to designate this disease, would illustrate the confusion that still exists in the minds of some observers regarding this symptom complex.

Erb (3) named this condition dysbasia angiosclerotica; Weir Mitchell (4) called it erythromelalgia, later he termed it vasomotor neurosis of the extremities; Walton termed it crural angina; others, intermittent claudication, *Gangstockung,* juvenile gangrene, presenile gangrene, spontaneous gangrene, obliterating endarteritis, local asphyxia of the extremities, acrocyanosis, acroasphyxia, acrosphacelus. Lannois (5) designates it as *paralysie vasomotrice des extremitiés.* By some it is described under the heading of pseudoerythromelalgia, nonsyphilitic endarteritis obliterans; still others have even used the designation Raynaud's disease to cover the above mentioned syndrome. In the past decade Buerger (6) suggested the term thromboangiitis obliterans, on the basis of the pathological changes present in the bloodvessels, and the extensive studies made by Buerger (6) have caused others to name the disease Buerger's disease. Osler (7) prefers to designate endarteritis obliterans as Friedlander's disease, or progressive sclerosis of the arteries. Local clinicians speak of this disease as Russian Jewish disease or Yiddish disease. This affection has often been confused with scleroderma, sclerodactylia, multiple neurotic gangrene, and acroparesthesia.

Not only has this disease been variously named, but many theories and hypotheses have been advanced to explain the phenomena associated with it. The earlier theories were chiefly concerned with the vasomotor and nervous elements of the bloodvessels. According to Erb (2), the disease was an angiospasm. This notion has been shared by only a few American observers, although most German clinicians have been inclined to accept Erb's view. In fact, the most recent publication on this subject, that of Schlesinger (8), emphasizes the vasoconstrictor element in this disease and bases the therapy almost exclusively on this phase. Others have considered it a neurosis, Weir Mitchell's (4) earliest publications describing this disease under the title of a rare vasomotor neurosis. Cassirer (9) and Oppenheim (10) lean toward this viewpoint and have grouped this syndrome under the vasomotor trophic neuroses.

Oppenheim (10) in his text book on nervous diseases considers this disease to be the outcome of a constitutionally defective nervous and vascular system. The majority of patients inherit not only a neuropathic constitution, but are congenitally afflicted with narrow bloodvessels, and a hypersensitive nervous system. He asserts that the stigmata of degeneration are quite common in patients afflicted with intermittent claudication, and there are other evidences of neuropathic disturbance. He is convinced that the disease begins as a functional disorder and after a varying lapse of years the injury resulting from unregulated flow of blood and constriction produces an organic change in the bloodvessels which leads to gangrene. He cites one case where angiospastic symptoms were present for eighteen years before it culminated in gangrene. Cassirer (10) shares this view and classifies the entire disease as a symptomatic group, subdivision being made according to the symptoms which predominate.

Another theory advanced by some clinicians is that vasoconstriction leading to gangrene is caused by the ingestion of certain toxic substances. According to some it was a form of ergotism due to the ingestion of spoiled corn or rye bread, and its frequency in people coming from regions where rye bread was extensively used was considered confirmatory of this theory. The fact that this disease had a predilection for the male sex in spite of the ingestion of rye bread by both sexes seemed to escape the notice of the adherents of this theory. More recently the theory has been advanced that nicotine plays a very important rôle in the etiology. There is a growing belief on the part of many people that nicotine is not entirely harmless and a great deal of experimental and clinical evidence has been gathered to show that nicotine contributes largely to the production of this symptom complex. Willy Meyer (11) in 1920 after having gone extensively into the bibliography is convinced that this is the etiological factor. Previous to this he attributed this condition to hyperglycemia, and constructed an ingenious theory to demonstrate that there was a high glucose content in the blood which he considered exercised a definite influence on the development of this disease. He termed this condition glycophilia, but abandoned this theory later in favor of nicotinism as the cause.

There are several factors, according to Meyer (11), which are responsible for its causation. First there is the hereditary factor which explains why this disease selects its victims, for the major part, among Russian and Polish Hebrews. These people having been persecuted for so many centuries have a very susceptible sympathetic nervous system, and lay themselves open particularly to the deleterious effect which nicotine exercises on the autonomic nervous system. In addition to this, they are inveterate and chronic smokers. The heavy work which they

are forced to do lays an added strain on the blood-vessels of the extremities. This, then, plus the perverse function of the sympathetic nervous system, induced by the absorption of poisons from tobacco smoke, produces contraction of arteries where there would ordinarily be relaxation, and so the symptom complex of the intermittent claudication occurs. The function of the eliminating glands is likewise diminished which permits accumulation of the tobacco toxins in the system. It is the pyridine in tobacco smoke which destroys red blood cells, and in addition affects the intimal lining of the bloodvessels. Tissue asphyxia results because of the accumulation of lactic acid in the muscle and body tissues which according to Meyer (11) is responsible for the bloodvessel lesions. This, in turn, causes intermittent limping or may culminate in gangrene. The value of this hypothesis in the light of actual researches will be discussed later.

The occupational theory has been advanced by some writers. The first reported case occurred in a sailor, while others affected were either soldiers or sailors in whom the extremities are severely taxed in their occupations. The advent of endocrinology has led other authors to seek the etiological factor in a disturbance of the ductless glands. Some have thought that its predilection for the male sex would be explained by the absence of some substance which ovarian tissue could supply. The therapy guided along these lines has, however, failed to produce any noticeable results. Still others have attempted to explain it on the ground of adrenalin deficiency, and have given adrenalin or adrenal gland containing compounds in the hope that a cure would result. The fallacy of this form of therapy will be discussed later. Tetany and its relationship to the parathyroids has suggested parathyroid medication without any better result.

Finkelstein (12) in New York has administered corpus luteum extract without any unusual result. Of those who lean to the infectious theory of this disease, the most prominent are Buerger (6) and Goodman (13) in this country. Buerger (6) is led to believe on the basis of his microscopical findings that some microbial agent is at the bottom of this disease, although extensive investigation has failed to disclose any type of organism. Goodman (13), on the other hand, believes that typhus fever plays the etiological rôle in this disease, adducing his belief from the fact that the majority of patients afflicted with thromboangiitis obliterans come from regions where typhus fever is associated with marked vascular changes, and is quite often followed by gangrene of the extremities, seems to him further proof that thromboangiitis obliterans is due to the organisms concerned in typhus fever.

Bernstein (14), in collaboration with Goodman (13), carried out serological investigations on thromboangiitis obliterans, and in three out of twenty cases found agglutinations and complement fixation with the organism described by Plotz (15). The value of this work in confirming the theory of Goodman (13) is negatived by the recent work of Schulz (16), da Rocha Lima (17), and Wollbach, who have definitely established that the bacillus of Plotz plays no etiological rôle in this disease. The recent publication of Olitsky (18), repudiating his earlier work proves conclusively that this organism is only a secondary invader, and therefore agglutination tests, with this organism, can be of very little value in deciding any causal relationship of typhus fever to this disease. The rôle that infectious diseases play in the production of arteritis is too well known to incriminate any special bacteria as the specific cause of this clinical syndrome. This will be discussed more fully in the summary of known facts concerning the production of this disease. The favor that focal infections have enjoyed in the past decade found its reflection in the theories advanced by some physicians that bad teeth or tonsils are responsible for this affection. It is quite true that the great majority of people affected with thromboangiitis obliterans have exceedingly bad teeth and infected tonsils, but little relief follows attention to these foci, in spite of their supposed relationship.

Mayeshima (19) in Japan, where this disease is quite prevalent, thought that the disease was due to the viscosity of the blood, and attempted to overcome it by the injection of Ringer's solution. The therapy that has been suggested along this line will be discussed more in detail under treatment. The viscosity theory is shared by Steel (20), who treated a small series of cases with sodium citrate in order to overcome the increased viscosity.

Acidemia theory.—The tendency to seek an explanation for this disease in an altered condition of the blood has led other workers to develop the theory of acidemia as the cause of this disease. Changes in hydrogen ion concentration of the blood on the acid side will lead to vasoconstriction, increased viscosity of the blood, increased tendency to coagulation of the blood and some of the other clinical manifestations present in this disease. Therapy directed towards combating the acidemia has given fairly gratifying results, which has tended to convince the adherents of this theory of its importance.

Combination theory in preexisting injury to blood vessels: A study of the history of a large number of these cases impresses one with the idea that in the majority of cases some preexisting injury to the bloodvessel has occurred, either as a result of frost bite or some traumatic injury subsequent to which infection of the bloodvessel walls developed with consequent arteritis and phlebitis. This is an added factor in the perpetuation of the disease and its progress.

The multiplicity of theories as well as the multiplicity of names suggested for this disease, indicate that we are dealing here with a group of symptoms due to a variety of causes, and while we may have a pathology which varies only slightly, the causes may be quite different. It would, therefore, be more logical to consider the condition of peripheral vascular disease as a syndrome due to a large group of etiological factors.

Some experimental proof has been recently furnished to show the truth of several of these hypotheses. Marcus (21), in Stockholm, has attempted to show that gangrene occurring in Raynaud's disease can be reproduced in a rabbit in whom the condition of local syncope is brought about by the intravenous injection of large quantities of adrenalin. If nothing further is done, a complete restitution to nor-

mal results, but if virulent streptococci are injected septic emboli develop in the constricted vessels of the ear, and gangrene results. This explains the phenomena observed in this disease where vasomotor symptoms may be present for years without gangrene, and then suddenly gangrene develops without any apparent cause.

KNOWN RESEARCHES

There has been comparatively little attempted in the way of experimental reproduction of this disease. Most of the investigations have been of a clinical order. For several years very little was known as far as the pathology of the condition was concerned, because so few cases came to autopsy. In Cassirer's (9) monograph he mentions that the first investigations that were made were those of Weir Mitchell (4), and these represented histological examination of resected toes and excised segments of nerve tissue. Weir Mitchell (4) and his coworkers were looking for nerve changes to explain the agonizing pains from which these patients suffered. He found very little in one case, while in a second case, which was relieved by operation, evidence of neuritis was present.

The first indication that this disease was due to bloodvessel obliteration was furnished by Sachs and Wiener (22) who examined the bloodvessels and nerves of a limb that had been amputated, and found evidence of obliterating endarteritis. Since then considerable work has been done by numerous workers, particularly on the pathological histology of the disease. Buerger's (6) work stands out because it has furnished an explanation for the retrogression of symptoms which is often observed, and which has led many observers to the belief that this condition represents a functional disorder of the nerves innervating the bloodvessel constrictor and dilator muscles. Buerger's (6) work has consisted chiefly in corelating first the condition of migrating phlebitis with this condition, and in pointing out that the inflammatory process involves the deeper bloodvessels as well as the superficial. The arteries, as well as the veins, are involved, the inflammation resulting in an increase in connective tissue. The detailed pathology of this condition will be discussed more fully below in connection with the pathology of the disease. It is this increase in connective tissue which binds bloodvessels and nerves together, and which is responsible for the agonizing pains. Putnam's histological investigations have concerned themselves chiefly with arteries and nerves, and he has found evidence of a neuritis present in addition to a vasculitis, thus confirming Weir Mitchell's (4) original finding.

Buerger (6) and Bernstein (14) have also investigated this disease from a bacteriological viewpoint, and although their investigations covered a large number of cases, they were unable to find in culture, stained sections, or by inoculation methods, any organisms of the spirochetal, acid fast or ordinary pyogenic group. Buerger (6) is convinced, nevertheless, that the histological changes in the veins and arteries point to the existence of an infectious process, and suggests that the infective agent be sought in the acute process in the superficial veins.

Barber (23), in Brooklyn, has similarly sought for the microbial agent of this disease and claims to have isolated in several cases a diplostreptococcus which grew slowly and appeared only in a special medium. In several cases which I have investigated, blood cultures were sterile with the exception of one case in which extensive thrombophlebitis and thromboangiitis were present, and in this patient a long chained streptococcus was isolated from the blood as well as from the affected veins and arteries of the thrombosed limb. The strain died out before it was possible to attempt inoculation experiments. This organism was likewise seen in smears made from the affected bloodvessel.

Marcus's (21) researches become of interest in this connection and may represent the link uniting the conflicting facts elicited in connection with this disease. He found that he could reproduce experimentally in rabbits a condition which he considered was identical with Raynaud's disease. He found that streptococci would localize in bloodvessels constricted by the use of adrenalin and would produce gangrene as a result of a localized thromboarteritis and phlebitis.

The search for indirect evidence of the presence of a microbial agent centred chiefly in immunological tests, first for the presence of the complement fixing bodies present in syphilis, and other infectious diseases, and then the agglutination tests carried out by Bernstein (25) in collaboration with Goodman.

Kaliski and Buerger (6), in 1910, found the Wassermann negative in a group of twenty-nine cases which they studied. The original Wassermann and the Bauer modification were used and controlled by the Noguchi antihuman system. All were cleancut negative although a control group of tertiary syphilis with and without vascular symptoms gave a fairly large proportion of positive tests. This has been the experience of most workers who have carried out Wassermann tests in this disease. The theory advanced by Goodman (14) that typhus fever was the etiological factor prompted him to carry out a series of agglutination tests with serum from thromboangiitis cases against the bacillus of Plotz (15). Out of twenty cases whose serum was tested for agglutination, three reacted with a somewhat increased titer. Aside from the fact that the bacillus of Plotz (15) has been repudiated as the causal factor, the agglutination tests themselves are certainly not conclusive.

Aside from Kaliski's and Buerger's (6) work, numerous workers have carried out complement fixation tests and have found them negative in the great majority of true cases of thromboangiitis obliterans. In a series of one hundred cases observed by the author, complement fixation tests were negative in all but two where a definite history of preceding luetic infection was obtainable. Investigations of the formed elements of the blood have similarly given little information. A curious fact is that a great majority of these patients have a rather high red blood cell count, as well as a fairly high hemoglobin concentration. Willy Meyer (11) had a series of thirty-four cases in which the average red blood cell count was over five million, and the hemoglobin about ninety-five per cent. The red blood cells do not vary from the normal as far as microscopical examinations show. This does not seem to

agree with Willy Meyer's (11) theory of the effect of pyridine on the red blood cells.

The white blood cells seem to be affected by the agent responsible for this disease. In a series of fifty or more cases the average white blood cell count was about 11,000; the lymphocytes exceeded their normal count by about ten per cent. A definite increase in the eosinophiles was present in the great majority of cases examined. The reason for this is not as yet clear.

The chemical pathology of this disease has interested investigators in the past few years, and the results obtained have been quite interesting. Kahn (24), in an unpublished investigation on a series of six cases studied at the Beth Israel Hospital, found the calcium content of the blood definitely increased in all cases. Bernhard (25) studied thirty-six cases and found the blood normal as far as its cholesterol, calcium ,and chloride content were concerned. The sugar content showed a definite variation from normal. In addition the glucose tolerance test showed definite variations which permitted the classification of these cases into three groups.

The entire group studied have a blood glucose content varying between 96 and 210 milligrams of sugar without any sugar appearing in the urine. The average in the blood for this group is 115 milligrams to 100 c. c. After the administration of glucose (100 grams), the following variation appears: One group of cases showed a rise varying from 106 to 344 milligrams (the average for all cases being 179 milligrams). Of this group thirty-six per cent. showed sugar present in urine, although almost one fourth of this number had a blood sugar of less than 150 milligrams, showing that the renal threshold for sugar was impaired. Six cases had a blood sugar content of 180 milligrams or over without glycosuria and sixty-nine per cent. had 150 milligrams or more. The renal threshold in the majority of cases was, therefore, higher than normal, indicating the deficiency in elimination previously mentioned in connection with Willy Meyer's (11) theory of the effect of nicotine on the causation of this disease. Two hours after the ingestion of the 100 grams of glucose, the blood sugar content varied between 96 and 288 milligrams, giving an average of 146 milligrams. Only thirty-three per cent. of these cases showed glycosuria. The great majority of these cases show a glucose tolerance curve which differs from the true diabetic and is significant because of the early rise and comparatively early drop, and also because of the renal retention of sugar which is present. The increased blood sugar which many of these patients have is dependent upon an increased hydrogen ion concentration of the blood, which not only occurs in this disease, but is present in many infections where a change takes place in the normal hydrogen ion—hydroxyl ion ratio.

Studies with regard to the coagulation time of the blood have likewise shown a deviation from the normal. The studies carried out by the author will appear shortly in another paper. A large number of patients affected with this disease show a markedly accelerated coagulation time which apparently explains the tendency to thrombosis of the affected bloodvessels which is so important an element in the production of many of the symptoms of this disease.

A number of other researches have been made which bear on this subject, but were not carried out as a part of systematic researches on thromboangiitis obliterans. These will be discussed in connection with the various symptoms under pathological physiology.

Author's bibliography will appear in his reprints.

What the General Practitioner Should and Must Know About Hypertension

HENRY HALPERT, M.D.,
Scranton, Pa.

Although blood pressure has been the subject of study and research since Harvey's discovery of the circulation of the blood in the middle of the seventeenth century, it is practically really only within the last decade that it has attained prominence from a practical viewpoint, in this country. This trend, however, had its beginning as far back as 1828, in Europe. Today its importance in the diagnosis, prognosis and treatment of disease is so great that its estimation is regarded as one of the essential factors in the general routine examination of every patient presenting himself with any constitutional ailment. And it is in this indirect way that deviations of the blood pressure from the normal are usually detected; or they may be brought to light during the progress of a compulsory examination prior to admission to an athletic contest or other physical strain, or following application for admission to college or camp life or, as it frequently happens, during a physical examination incident to the obtaining of a life insurance policy. In nearly every pathological condition there is a change of blood tension; in some cases it is influenced to rise above the normal limits, and in other cases the variation is in the reverse direction.

Blood pressure is dependent upon the following factors: the vasomotor system, the strength and energy of the heart, the elasticity of the vascular system, the volume of the circulating blood, and upon the peripheral resistance. Any element which disturbs the harmony of this system will, in turn, affect the blood pressure. The history of blood pressure determinations may be traced back to 1828, when Poiseuille introduced the first U tube manometer. But it was not until 1876 that a useful blood pressure apparatus was devised by Marey, by

means of which both systolic and diastolic blood pressure could be recorded. All modern sphygmomanometers, however, utilize the pneumatic principle of Riva-Rocci, who devised his instrument in 1896 employing a pneumatic constricting band. The essential difference in sphygmomanometers of today, as compared with that of Riva-Rocci, is the greater width of the cuff. This is now from twelve to fifteen cm. wide, the original narrower cuff being found to give to higher readings on account of loss of pressure in compressing the tissues. Theodore Janeway, in high tension cases, found a five cm. cuff to register as much as 60 mm. higher than a twelve cm. cuff. To estimate blood pressure accurately on instruments of the modern type, the usual procedure is as follows: The apparatus having been set up, the pneumatic cuff is adjusted snugly and without compression to either arm or thigh—usually the former. The cuff is then inflated until the pulse below the constriction is obliterated. Estimation of blood pressure is then made by either of two methods: the old, or palpation method; the new, or auscultation method. Systolic and diastolic pressure may be estimated by either method.

A determination of blood pressure in the past meant merely a reading of the systolic pressure, without any consideration of the diastolic or of the pulse pressure. This was largely due to the difficulty in obtaining reliable readings of the diastolic pressure. Pulse pressure being the difference bebetween the systolic and diastolic pressure, depended upon the correct estimation of both these factors. The significance of pulse pressure is, in the opinion of many observers, greater than either the systolic or diastolic, for the following reasons: Pulse pressure depends upon pulse rate. If the pulse is slowed, more time is allowed for the blood to run through the arterial system during systole. Diastolic pressure will be lowered and pulse pressure increased; the reverse is also true. A weak heart will not raise tension as rapidly as a strong one, and the interval between the end of each systole and the next will be shorter and the pulse pressure lower. In a stronger heart the interval between systoles is longer and there is a larger pulse pressure. During contraction of bloodvessels, the diastolic pressure will be found to remain high, giving a small pulse pressure, and vice versa. A low systolic pressure with a large pulse pressure, probably indicates dilated vessels and a strong heart; while a low systolic pressure with a slight pulse pressure indicates a weak heart, and perhaps some dilatation of the vessels.

Not only is pulse pressure important in determining whether the present condition of the patient is due to deficiencies in heart or arteries, but it also serves, during treatment, as an accurate indication of results being obtained.

On the whole, however, too much significance should not be attached to these factors to the exclusion of all others, for it is urgent that all widely diversified symptoms be given their just evaluation, and that they be regarded from a clinical standpoint; and, further, that a correlation of existing conditions be not neglected.

The fact that the employment of special apparatus in the estimation of blood pressure has, to a great extent, superseded the old methods of palpation is viewed with disfavor by many observers. By them, the fingers are still considered the most reliable and sensitive of instruments, for through them is obtained not only an intelligent appreciation of the pulse beat, but the knowledge of interpretation of the sensations acquired by experience in this form of observations.

The position of the patient is an influencing factor in a determination of pressure, systolic pressure being eight to ten mm. higher in the reclining than in the sitting position. About the same difference will be found between the sitting and the standing posture. The diastolic pressure also rises but relatively higher than the systolic, and pulse pressure is consequently increased. The pulse rate is also increased. For these reasons it is important to take subsequent readings of the same patient in the same position as during the initial procedure. These determinations are best made midway between meals.

Another fallacy, in addition to those referred to before, was the former belief that hypertension was a condition peculiar to old age. It has now been determined beyond a doubt that variations of blood pressure are present at all ages and in a great variety of conditions. In children, according to Melvin and Murray (1) the average systolic pressure is only slightly lower than in adults; the average diastolic level, on the other hand, is decidedly higher than in adults, according to these writers. By the tactile method the average systolic pressure was 105.7 in a large series of children, as compared with 108.7 in adults, while the range was 125-84 in the former and 132-92 in the latter. In children the relation of pulse pressure to systolic pressure was 1 to 3 and the diastolic 1 to 2, while in adults this relation was 1 to 2.7 and 1 to 1.6 respectively.

In regard to the variation as influenced by sex, Faber and James determined (2) that mean systolic pressure shows no significant differences between the sexes within the period ranging from four to sixteen years. Further, that mean diastolic and mean pulse pressure do show significant sexual differences. Standard deviations were in all cases greater for girls, indicating a normally greater variability in female children, particularly marked during adolescence.

The actual cause of hypertension is still obscure however, many factors are believed generally to be provocative agents. Excessive indulgence in stimulating foods and drinks, especially abundant use of proteids, overindulgence in exercise, mental strain or worry, the emotional factor, disturbances of the ductless glands, change of function such as exerted by the menopause, the rôle of certain poisons and infections including syphilis (3), the disturbance of salt metabolism, excessive drinking and even the influence of heredity are among the large number of factors held responsible.

The consensus of opinion of the usual cycle has recently been well expressed by Osborn (4): "The cause of hypertension in the average individual of the present day is excessive use of stimulating foods especially abundant use of proteids, these foods causing the circulation, after the immediate stimulating

ffects have passed off, to become depressed. This, epeated for several years, will finally, through al- ered blood supply to the ductless glands, bring about derangement of their normal function. The har- nony is broken and they are impaired. The endo- rine glands have a marked influence on the forma- ion of the blood, also blood pressure is greatly in- luenced by them. If these glands are not properly ourished, they will become deteriorated and their unction greatly impaired or lost altogether. If verstimulated by food products, continued over- ction will give rise to exhaustion and there will be legenerative changes with inactivity.

The metabolic and nutritive processes of all the rgans and tissues of the body depend upon the roper function of the ductless glands. These grad- ally undergo impairment as we grow older, as do ll tissues of the body. This impairment may be astened by improper and oversupply of these food roducts which, through their stimulating effect, roduce exhaustion of the glands. Hypersecretion omes about by an excessive form of poison or toxic naterial within the blood stream, and it is probable hat there is some relation between disturbances of nternal secretion and the vascular tonus."

It is regrettable that our judgment of etiological factors is necessarily hampered by the fact that most patients with hypertension are not seen by the physician until the patient has reached the age at which arteriosclerotic changes appear which are associated with the onset of old age. The frequent association of certain renal lesions, also, with hypertension, has led to the deduction that these lesions were the cause of hypertension. In fact, the question of the definite interrelation of hypertension, arteriosclerosis and certain forms of nephritis has been a much discussed one, to which the recent theory of Moschcowitz (5) is a valuable contribution. This writer believes that hypertension is an important—if not the most important—factor in producing the lesion of arteriosclerosis; that arteriosclerosis and arteriocapillary fibrosis of the kidney are one and the same lesion and are always associated, and that, therefore, hypertension is the most prominent cause of arteriocapillary fibrosis of the kidney. According to this theory, the arterial and renal lesions are not separate and distinct entities, bearing mutual relations to each other, but are simultaneous results of the same condition. This relationship is definitely opposed to the theories generally accepted, firstly, that hypertension is caused by renal injury or the group of injuries termed chronic interstitial nephritis; and, secondly, that whatever the cause of hypertension, the end result is either an arteriosclerosis of the terminal arteries, including those within the kidney, or a damage of the kidney parenchyma itself in variable proportions.

In the typical high tension case, the heart is found to be hypertrophied, there is high arterial tension and an increase in the amount of urine. A series of questions directed to the patient will reveal symptoms of disorder of the cerebral circulation, as indicated by a subjective feeling of nervousness, headache, possibly nosebleed, insomnia or attacks of dizziness, or even threatened aphasia and hemiplegia.

The early symptoms of hypertension are often an unhealthy appearance, loss of strength, and such disturbances of digestion as may be referred to a weakened condition. The urine may contain albumin only occasionally, so that for this as well as for the detection of variations in blood pressure it is essential to examining these patients repeatedly as well as thoroughly.

In addition to conditions already referred to as being associated with hypertension such as arteriosclerosis and nephritis and the like, the following may also be included: Uremia, apoplexy, cerebral thrombosis, fracture of the skull, intracranial hemorrhage, cerebral tumors, Jacksonian epilepsy, idiopathic epilepsy, angina pectoris, aortic regurgitation, impaired heart conditions, gout, lead poisoning, exophthalmic goitre, diseases of the eyes, obstetrical conditions, particularly at the end of pregnancy.

A systolic pressure of 150 or 160, with a diastolic pressure of 60 or 70 and, consequently, a pulse pressure of about 100, are not infrequent in patients with a gross lesion of the heart, according to Cowan and Ritchie (6), "in the lesser lesions, on the other hand, the systolic and pulse pressure may be within normal limits, such as 120, 40; 125, 35; 115, 20. As a rule, however, both figures are greater than normal: 155, 55; 150, 60; 135, 50."

From the numerous and varied conditions with which blood pressure is found associated, it at once becomes evident that treatment of hypertension cannot be undertaken without a complete understanding of the other conditions coincidently present.

It seems logical, therefore, that the regulation of diet will exert a beneficial influence on hypertension. It should be begun early and followed systematically. Avoidance of all foods which tend toward overstimulation is a valuable preventive measure as well as an efficient form of treatment for advanced cases. The salt and fluid intake are of great importance. It is also essential that elimination—preferably by the nondrug treatment—should receive the proper attention. Physical rest and complete relief from mental strain and worry, with full attention to physical hygiene generally, and abstinence from smoking, alcoholics, tea and coffee, will go a long way toward relieving tension. A systematic form of exercise, preferably in the open air, will be found of value in some cases, while selective baths, high frequency, the Nauheim treatment, venesection, and other treatments are indicated in others.

The point cannot be too greatly stressed that, in all cases, treatment must depend in great measure upon the correctness of the diagnosis. One should not be in a hurry to lower tension in all cases, for it must be borne in mind that in some cases it is compensatory.

The drug treatment is considered, on the whole, less satisfactory than the drugless treatment. Some writers believe that digitalis, when employed, should be accompanied or preceded by some eliminative. According to others, this drug may produce an elevation of blood pressure with consequent rupture of cerebral vessels. In my experience digitalis, judiciously given in hypertension with irregular heart acts well—and I am never afraid to give digitalis in my hypertension cases, when indicated. The nitrates, especially nitroglycerine, or, more recently, benzyl benzoate, have been employed in cases of hyperten-

sive heart disease. In hyperthyroidism, glandular therapy may be indicated; in rheumatic diathesis iodine preparations, either internally or externally, give relief in most cases. In gouty cases, atophan acts sometimes remarkably well. Iodide of potassium reduces the hypertension effectively oftentimes.

To sum up, suggestions to be offered for the relief of high blood pressure cases are legion, and in each instance must be greatly influenced by the accompanying conditions.

SUMMARY

Accuracy in the estimation of blood pressure, arrived at after frequent determinations over a long period preferably, followed by the proper evaluation of conditions leading to a correct diagnosis, together with the employment of restrictions of diet, proper hygienic measures—alone or combined with the administration of drugs, if indicated—make for a likelihood of the relief or cure of hypertension.

Clinical Studies in Venous Thrombosis

Its Occurrence and Significance in the Course of Advanced Heart Failure

DAVID GREENBERG, M.D.,
New York

The phenomenon of thrombosis is so frequent that it is hardly the scope of a single paper to enumerate even briefly the conditions where it may occur. This is especially true if one includes frankly bacterial thromboses, such as sinus thrombosis following purulent otitis or pampiniform plexus thrombosis following pelvic inflammation and pyelophlebitis, following appendiceal infections. Capillary thromboses perhaps occur even more frequently as manifested by various petechial and microscopic focal necroses in the various blood dyscrasias and in septic or toxic conditions. These bacterial and capillary thromboses are fairly well understood and will not be included in our present discussion.

There is, however, a group of venous thromboses involving the larger vein trunks apparently unassociated with bacterial infections—socalled bland thrombi—which are relatively rare. They are met with in chronic wasting diseases and cachectic conditions such as tuberculosis, cancer and chronic heart failure. The etiology of these thromboses is still under discussion. Virchow, Aschoff and their pupils explain these thromboses largely on a mechanical basis, giving as the chief factors, first, alterations in the composition of blood, secondly, alterations in the rate of blood flow (with stagnation), and thirdly, peculiarities in the vascular wall. These authors emphasize the valves in the veins, tortuosities, varicosities, causing eddying of the blood with socalled sandbar formation among other things as contributory factors in the formation of such thromboses. Other observers, notably Vaquez and Widal, in France, assert for bacterial infections with a phlebitis or endophlebitis, a most significant rôle in the causation of the thrombi. They emphasize the frequency with which bacteria may be demonstrated in such thrombi on postmortem examination and reject the assumption that bacteria only invade these areas in the preagonal and agonal stages. A survey of the literature convinces one that both mechanical as well as bacterial factors probably play important parts in the causation of bland thrombi, and that a combination of circumstances is perhaps a necessary prerequisite. There is indubitable published evidence in support of both the mechanical and the infectious theory of thrombus formation.

The nature of the thrombus has received considerable study. It is generally believed that they begin at first as platelet thrombi, to which are later added the other elements, leucocytes, fibrin and red cells, making up the whole thrombotic mass. In size they vary greatly according to the size of the vessel, the proximity of branches and the condition of circulation. They often attain a considerable size and usually flow in the direction of the blood stream. To the platelet thrombus there is soon attached a less firm portion, darker in color, consisting of fibrin enmeshing leucocytes and erythrocytes forming the body or tail of the thrombus. This process sometimes extends until the next open branch is reached, when a new platelet thrombus may form with a repetition of the process, so that one often sees long thrombi consisting of alternating small areas of platelet thrombus (white thrombus) with larger areas of red thrombus. Occasionally these thrombi undergo further changes. Becoming infiltrated with fibroblast, they may be converted into connective tissue and be indistinguishable from the scar tissue of the vascular wall to which they are firmly adherent. More rarely they become canalized and circulation may be reestablished through them. When portions of these thrombi become detached and are conveyed to the right heart they give rise to embolism in various organs especially the lung.

In chronic heart failure such thromboses occur without any significant evidence of bacterial infection. They may, therefore, be classified as belonging to the group of bland thrombi. Considering the great frequency of heart failure, thromboses may be said to be rather rare. They involve the lower ex-

tremities—saphenous or popliteal veins as well as the upper extremities and the sinuses of the dura mater do not escape. When they occur they usually aggravate considerably the condition of the patient and are almost invariably of grave prognostic significance.

To illustrate the gravity of this complication in heartfailure the following case histories will be summarized.

Case I.—Mrs. L. B., aged fifty-six years, Russian Hebrew, with a negative family history and irrelevant previous history, came under observation in September 1917. For about a year previously she had shortness of breath on walking up stairs, a sense of discomfort over the precordium and palpitation. Three days before she was seen she became very dyspneic, and coughed a great deal after a walk of about half a mile. Examination showed a fairly well developed, well nourished female who looked ill and anxious. The heart was enlarged downward and to the left. The apex beat was diffuse and in the sixth interspace there was a systolic rough murmur over the whole precordium, especially loud over the apex and aortic areas. The second aortic sound was accentuated. While listening to the apex a premature contraction was occasionally heard. The lungs showed stasis at both bases with some consolidation at the right base posteriorly. The liver was palpable and somewhat tender. There was clubbing of the fingers and toes. There was no edema or ascites. The pulse was 100 at the apex and 93 at the wrist. The temperature was 101° F., respiration 30 a minute, blood pressure 175 systolic, 95 diastolic, both arms. The urine showed a moderate amount of albumin and a few hyalin and granular casts. Phenolsulphonephthalein output was 45 per cent. in two hours. The patient improved rapidly on digitalis medication and rest so that she felt well enough to be up and about in ten days. She remained fairly comfortable for the ensuing three and a half months.

Early in January 1918 evidence of decompensation again became manifest. This time there was more fever (102.5° F) and there was also hemoptysis. There was definite evidence of heartfailure with pulmonary stasis. She improved considerably after two weeks in bed and for the following two months she was able to be up and about most of the time.

In March she had to take to bed again because of shortness of breath and edema of the ankles. Her liver this time was at the level of the umbilicus and pulsating. She was suffering from a marked degree of auricular fibrillation (absolute irregularity) and a pulse deficit of 15 (apex 115, radial 100). Soon thereafter her dyspnea became more marked and she developed moderate cyanosis. At this time, because of a distinct murmur over the tricuspid area with pulsating jugulars and liver, a diagnosis of tricuspid insufficiency was made. Toward the end of March she began to complain of pain in the left lower extremity, which was tender along the course of the veins, popliteal and saphenous. On March 28th it was noticed that the left leg and thigh were very much more swollen and harder than the right, the circumference of the calf and thigh on the left side being about double that of the right. The edema gradually extended upward involving the lower abdomen and back after about a week from the onset. The temperature did not vary much from the preceding course, being rather irregular and varying between 98 and 100 8/10. The pain and tenderness, however, were distressing. There was no leucocytosis.

About April 10th the right upper extremity became tender and on the next day it became edematous. The tenderness was especially marked over the course of the veins and the edema was tense, beginning in the forearm, lower arm and gradually extending toward the axilla. Her condition remained stationary until about May 18th, when pain, tenderness and edema of the left upper extremity developed. A definite mass of veins could be made out in the supraclavicular space. They felt like a varicocele and were very tender. From now on the clinical course was progressively downward. She became drowsy, more cyanotic and ascites, stasis pneumonia and a decubitus ulcer developed.

On June 18th she was observed to have a double exophthalmos with some rigidity of the neck. This was thought to be due to sinus thrombosis of the dura. Her eye grounds could not be examined because of double cataract. The cerebrospinal fluid was under pressure, but otherwise negative.

She died June 23, 1918, three months after the onset of venous thrombosis.

Case III.—F. K., Hospital No. 37317, female, aged twenty-eight years, was admitted April 19, 1922, complaining of dyspnea, cough and swelling of ankles, of five weeks' duration. Her family history as well as past history was irrelevant, except for a nonproductive cough some three months prior to admission. She had one pregnancy and her child, who is nine months of age, is well. During her pregnancy she had swelling of the left lower extremity which disappeared after the birth of her child.

Examination revealed an acutely ill woman, flushed and somewhat cyanotic. Her teeth showed some caries. There was dullness over both bases posteriorly. Sibilant and sonorous râles were present over both lungs. The heart was enlarged to the right. The first sound was of poor muscular quality with an indefinite murmur at the apex. The liver was palpable but not pulsating. She had a temperature of 101° and her pulse was rapid. Her legs were not swollen.

The blood count was normal. The urine showed a moderate number of pus cells and a few hyaline and granular casts. The phthalein output was ten per cent. in two hours. The blood chemistry was normal. A diagnosis of influenza was made and she was treated accordingly.

After several days' rest in bed with moderate doses of digitalis she improved slowly, so that after a month's stay in the hospital she was afebrile, felt well, had no shortness of breath or cough. She was discharged May 17, 1922, greatly improved.

She was readmitted on May 22, 1922, because of the reappearance of her symptoms twenty-four hours previously. On her second admission she was restless, dyspneic and cyanotic. The heart sounds were of poor muscular quality, rapid and an occasional premature contraction could be heard over the pre-

cordium. A loud systolic murmur was heard over the apex and it was transmitted to the axilla. The pulse was small, thready, of poor quality, with a deficit of ten at the radial. The lungs showed some evidence of stasis. The liver was palpable but not pulsating and there was moderate edema of both ankles.

Three days after admission her condition appeared to be somewhat improved. There was less dyspnea, her pulse was better and her color was not as bad as on admission. She soon relapsed, however, and developed repeated attacks of extreme heart failure with marked cyanosis, extreme dyspnea, poor and rapid pulse and signs of impending dissolution. These attacks would last anywheres from one to several hours.

About July 5th pain and tenderness developed in her left lower extremity. Edema of the same extremity appeared two days later and extended up to the middle of the thigh. This edema remained more or less stationary. About July 31st suddenly there developed pain in the right chest and a severe cough. Signs of consolidation were elicited several days afterward. With this her temperature rose to 104° and fluctuated between 104 and 99 for the ensuing period of her stay in the hospital. The blood examination showed hemoglobin 99 per cent., red blood cells 4,500,000, white blood cells 14,200 with 84 per cent. polymorphonuclears and 16 per cent. lymphocytes. The urine showed hyaline and granular casts. The blood pressure was low throughout, 86 to 90 systolic and 70 diastolic (low pulse pressure). Her Wassermann was negative. She died August 15, 1922, in one of her attacks of tachycardia and cyanosis. Death occurred a little less than six weeks after the onset of venous thrombosis in her left leg.

COMMENT

From a perusal of the literature one is inclined to believe that thrombosis is an infrequent complication of heart failure. Bouchut (1) reported it in 1845. Baldwin (2) in 1897 called attention to it in this country and reported one case out of thirty-four as occurring in heartfailure. Welch (3) in his extensive studies of thrombosis and embolism, reports five cases of his own and twenty-three cases from the literature. Blumer (4) reports one case out of four as due to heart disease. Poynton (5) reported three well studied cases associated with rheumatic heart disease. Futcher (6) reports a case similar to Case IV herein reported.[1] His case subsequently developed embolism of a large artery. Brannan (7) reported a case also similar to Case IV except that in his case the thrombosis occurred in the right side. Huchard (8) and White (9) also describe the condition as occurring in heart failure.

More recently, however, Sladen and Winternitz (10) reviewed the subject rather comprehensively up to 1915 and report seventeen cases of their own (the largest series up to date by one set of observers). These authors emphasize the fact that thrombosis in heart failure may be overlooked frequently because of the already existing edema. With this view my observations fully agree. Unless looked for carefully by comparing the two limbs and palpating along the course of the large veins where tenderness may almost invariably be elicited, the condition is often missed.

The gravity of this complication has been stressed by most of the authors writing on the subject. The case histories in this article cannot fail to impress the reader with the seriousness of this complication. All of my patients died within a comparatively short time after the first appearance of venous thrombosis. Whether the thrombosis *per se* hastens death or whether it merely is an expression of the gravity of the condition I am not prepared to say. In Case I the development of sinus thrombosis and in Case III the development of probably embolic pneumonia most likely shortened life.

It is generally believed that in heart failure thrombosis of the upper extremity is more frequent than that of the lower extremity. In this small series of cases the incidence of upper and lower extremity involvement is about equal. The prognosis is equally bad whether upper or lower extremity is involved or both. The number of extremities or rather extent of involvement appears not to influence the outlook. According to Sladen and Winternitz the mortality is about eighty-three per cent. The frequency with which embolism may occur is a subject worth while studying. The idea suggests itself that perhaps many of the socalled stasis pneumonias may be embolic from an unobserved venous thrombosis. This condition may be also mistaken for cardiac thrombosis when emboli occur in the peripheral vessels without the presence of bacterial endocarditis, for a potent foramen ovale is not as rare as is usually believed.

The treatment of this condition is at present unsatisfactory. The primary heart disease should of course be treated thoroughly. The question of passive motion and massage to the extremities before the onset of thrombosis should be considered in all cases of heart failure.

CONCLUSIONS

From a study of these cases it may be stated that

1. Venous thrombosis not infrequently occurs as a result of chronic heart failure and it may be overlooked because of the associated edema.

2. The site of such thromboses may be either in the vessels of the extremities or sinuses of the brain and perhaps in the deep veins of the thorax and abdomen.

3. When such thrombosis occurs it renders the prognosis extremely grave.

4. It is possible that passive motion of the extremities together with massage may be indicated in some cases of chronic heart failure.

Local Anesthesia for Dental, Oral, Nose and Throat Surgeons

*Fourth Article**

H. E. TOMPKINS, M.D., D.D.S.
New York.

(*Concluded from page 223*)

LOCAL ANESTHESIA FOR TONSILLECTOMY

The tonsillar area is innervated by branches from Meckel's ganglion, by the faucal branch of the lingual and by branches from the pharyngeal plexus which form, on the tonsil, the tonsillar plexus. Meckel's ganglion may be anesthetized by one of the regional or conduction methods already described but the other nerves must be anesthetized by practically infiltration methods.

The pharnygeal plexus lies just under the aponeurosis on the belly of the superior constrictor muscle, its branches rise and enter the tonsil with the aponeurosis or as it is called, the capsule. So it will be seen that to anesthetize the tonsil the solution must be injected near the pedicle and just beneath the aponeurosis or in other words, between the superior constrictor muscle and the aponeurosis near the pedicle. The principal branches from the pharyngeal plexus rise directly to the pedicle, some minor branches rise higher then turn and drop to the pedicle, the branch from the lingual also drops to the pedicle. Thus it will be seen that solution must be deposited both above and below the pedicle.

The needle used is twenty-five mm. in length and of twenty-one gauge. This large gauge is used to enable the operator to direct the needle without fear of bending and thus lose direction. The needle is entered into and through the anterior pillar at a point where it will pass between the aponeurosis and the superior constrictor muscle about three mm. above the pedicle. The needle is advanced until its point is just about on a line with the posterior border of the posterior pillar and under the body of the pillar. On passing the needle into the tissue and also during its withdrawal, one mil of one per cent. solution of procaine, containing suprarenal extract in the proportion of one to 50,000, is injected. This injection is duplicated at a point beneath the pedicle and in the same relation to the parts.

While making these injections the needle must at all times be directed toward the median line. It never should be allowed to pierce and go through the superior constrictor muscle for the reason that external to that muscle considerable danger lies and because the nerves to be anesthetized lie just beneath the mucous membrane.

FOR OPERATIONS ON THE TONGUE

The anterior two thirds of the tongue or that portion anterior to the circumvallate papillæ is innervated by the lingual nerve. The posterior third or that portion of the tongue back of and under the papillæ is innervated by the glossopharyngeal.

Anesthesia of the lingual nerve is readily produced by regional or conduction methods according to the technic described under the injection at the inferior dental foramen, advancing the needle to the position of the lingual nerve only. It must be remembered that the lingual nerve lies about five to six mm. under the tissue, close to the internal oblique line. To produce anesthesia of the lingual nerve, about one mil of one per cent. procaine solution is injected, at the site indicated. The resulting anesthesia involves the area to which the branches of the lingual nerve distribute, namely, the anterior two thirds of the tongue proper, by the lingual and a portion of the sublingual branches; the mucous membrane of the floor of the mouth, the alveolus and the sublingual area, by the sublingual branch; and, that area to the side, back of and slightly above the tongue, in the region of the tonsil, as innervated by the faucal branch of the lingual.

The posterior portion of the tongue, from the circumvallate papillæ to its root, must be anesthetized by infiltration for the reason that there is no single place at which to inject any of the lingual branches of the glossopharyngeal. The lingual ramifications of the superior laryngeal may be anesthetized by regional methods (as set forth below) but since infiltration is necessary for the lingual branches of the glossopharyngeal, it does not seem wise to use the regional method. Again, it is extremely difficult to delineate, with any accuracy, the extent of the area of anesthesia produced by the injection of the trunk of the lingual branch of the superior laryngeal and, further, the ramifications of the terminal branches of each overlap.

REGIONAL ANESTHESIA OF THE SUPERIOR LARYNGEAL

It is desirable in many cases to operate on the larynx without the topical application of an anesthetic drug which must be applied in high percentages. In tubercular laryngeal cases, it may be thought well to make alcoholic injections, the technic of which is exactly the same as for the production of regional anesthesia. In operations on the larynx, from the outside, and in other operations on the throat, regional anesthesia is especially desirable because of the smaller amount of anesthetic solution required and because of the greater area of anesthesia produced.

That a clear mental picture may be had, let us review the course of the superior laryngeal through its safely and easily accessible area. The accompanying picture may help to recall the position of this nerve. These pictures are old, so, too, is the terminology, but I know of no work which pictures the area so well. These pictures are taken from *Weisse's Practical Anatomy* (1899).

It is seen that the superior laryngeal passes close to the greater cornu of the hyoid, extending downward, forward and outward for about ten mm. to a point about midway between the hyoid bone and the thyroid cartilage where it enters the thyrohyoid

*The first article in the series was published in our issue for October 19, 1921; the second in February 1, 1922, and the third in March 1, 1922.

membrane. Immediately after entering the membrane, it divides into the internal laryngeal which is the source of sensation of the larynx the external laryngeal whose function is to supply some sensory but mostly motor impluses to the cricothyroid muscle; and the communicating branch which passes downward and joins the recurrent laryngeal, which, according to Allen, "is distributed to all muscles except the cricothyroid and supplies sensation to all parts below the vocal cords."

Thus it would seem that injection of anesthetic solution at the accessible part of the trunk of the superior laryngeal would produce anesthesia in the base of the tongue, the larynx and surrounding hyoid and thyroid muscles, but not the skin and the platysma.

In his *Local and Regional Anesthesia* (1914), Dr. C. W. Allen says:

"To reach this nerve for regional infiltration have the patient lie on his back, with a small pillow under the back of his neck; have an assistant, by pressure on the opposite side, displace the hyoid bone from one side, rendering it more prominent; with an index finger on the great cornu, the needle is passed down in this direction and two or three c. c. of 0.5 per cent. procaine with one drop of adrenalin (one to 1,000) is injected into the thyrohyoid membrane, a little below and in front ,about one half inch) of the great cornu; the opposite side is treated the same way; the anesthesia appears in from five to ten minutes and frequently lasts one hour or longer, and is sufficient for all operations above the vocal cords.

The method described above is perfectly clear—to the man who has performed the injection several times. It is not sufficiently clear to enable the neophyte to accomplish the work. The writer has sought and found two landmarks which may enable the operator to work more intelligently.

The patient is placed on his back with a rest under the neck so that the head is thrown well back, thus exposing the full neck.

The larynx is displaced to one side. On the now more prominent side, the greater cornu of the hyoid bone is palpated; the highest point of the curvature of the ala of the thyroid is also palpated, this latter point is from five to ten mm. posterior to the upper angle of the notch of the cartilage and on its upper border. An imaginary, or if necessary, an actual line is drawn between the two points palpated.

At a point about one third of the length of the line, from its anterior end, the needle is inserted into the tissue in a median direction. The needle is advanced until it shall have pierced the platysma muscle and the overlying and underlying fatty tissue. In the average case the distance is approximately five mm. The body of the syringe is now swung to the front into such a position that the needle will be parallel with the line drawn and the point of the needle—if it were advanced sufficiently far—would pierce the greater cornu of the hyoid. In other words, the needle is directed straight for the greater cornu of the hyoid. The needle is advanced in the direction given for a distance of approximately ten mm, or to such an extent that the point of the needle is about five mm. from the greater cornu. While making this advance the needle pierces the various hyoid and thyroid muscles encountered and when the advance has been completed, the needle lies in the space between the muscles and the thyrohyoid membrane. The presence of the needle in this space is determined by releasing the larynx. The needle is felt to be in a socalled empty space.

At this point one to one and a half mils of one per cent. procaine solution is injected, slowly. During the progress of the needle to this location approximately one half mil of solution has been injected just ahead of the needle to make its advance painless.

The needle follows closely the course of the laryngeal branch of the superior laryngeal, in a reverse direction of course, back to and beyond the point at which the trunk splits into its various branches. It is evident that injection of the larger amount of solution before the needle has reached the specified point will not produce the desired anesthesia because of the fact that the trunk of the nerve enters the thyrohyoid membrane at approximately the end of the ten mm. advance. Deposition of solution outside of the membrane or before the trunk has been reached may produce some anesthesia but the desired depth and extent will not and cannot be produced unless the solution be deposited along the course of the trunk itself and within no greater distance than five mm. from the trunk.

Care must be taken that the needle does not enter nor pierce the thyrohyoid membrane. Between the membrane and the interior of the larynx lies only a thin layer of connective tissue, through which travels the blood and nerve supply, and the mucous membrane. It is evident that by allowing the needle to pierce the membrane, it very easily enters the interior of the larynx and while this is not especially dangerous, it is not exactly desirable.

Care must be taken, too, that the patient shall not swallow during the insertion of the needle.

The anesthesia resulting from this injection will cover all of that area to which the various branches of the superior laryngeal are distributed and will present in from five to fifteen minutes.

Accidents.—The thyrohyoid membrane may be punctured. Proper directional placing of the needle will obviate this. The internal laryngeal artery or vein may be punctured. If a needle of large gauge, with its point ground at an angle of 45°, is used little danger of such an accident presents.

The use of old, discolored or nonisotonic solutions will be followed by soreness, sloughing, fainting, shock or collapse.

Infection and dangerous abscesses will follow the use of unclean instruments or solutions.

CONCLUDING REMARKS

In certain areas conditions may exist which prohibit the use of the injections described; in fact, the use of local anesthesia may be proscribed. In those cases, particularly in the dental areas, certain socalled extraoral injections may be made; in my opinion it is better to use general narcosis.

The surgeon, when making injections for local anesthesia, is to remember that all injections into bony areas *must* be made slowly; injections into soft areas *may* be made quickly. General safety, freedom from shock, fainting or collapse demand that *all* injections in any area be made slowly.

Practical Therapeutics

CLINICAL EXPERIENCES WITH DESICCATED SPLEEN AND RED BONE MARROW IN THE TREATMENT OF ANEMIA

H. M. Kay, M.D.
Madison, Wisconsin

In a preliminary clinical report, Leake and Evans (1) state that desiccated spleen and red bone marrow, combined in equal proportions by weight, and administered in five grain (0.3 gram) amounts in capsules three times daily, has been found beneficial in certain types of anemia. These were listed in the order in which greatest improvement was noted, as follows:

1. Grave chronic secondary anemias of undetermined origin, having many of the characteristics of the progressive pernicious type (high color index, abnormal forms of erythrocytes, marked pallor, dyspnea, and cardiac disturbances), and in which iron and arsenic, and in some cases transfusions, had failed to bring about a favorable response.
2. Grave active secondary anemias of acute septic infections.
3. Chronic anemias found as an accompaniment of chronic infections.
4. Dietary anemias of infants, in which if the patient is too small to take capsules, the preparation is administered in boiled and filtered aqueous solution as a broth.
5. Menorrhagic anemias.
6. Mild chloroanemias of adults.

The preparation was not found beneficial in pernicious anemia. These clinical observations followed the experimental reports previously made by Leake (2), in which it was claimed that desiccated spleen and red bone marrow, administered as noted above, were efficient erythropoietic agents in normal humans, and more powerful as such, in combination, than when used singly.

It is to be realized at once that this type of treatment of anemia is only symptomatic, and while it may be of great value in improving the patient's general condition, it does not constitute in any sense a cure for anemia, unless it contributes to the discovery and removal of the cause.

One must approach the question of the symptomatic treatment of anemia with extreme skepticism, in view of the long clinical experience with arsenic and iron and the present disagreement as to their value in this condition, and in light of the many factors which may contribute to a spontaneous remission unrelated to any form of treatment. Furthermore, the most careful technical work reveals that wide fluctuations of the erythrocytes and hemoglobin content are encountered even in normal and healthy individuals, so that the limits of definite change must be placed at least at plus or minus five per cent. with the most careful technic, with the determinations made at the same hour daily, and with no marked variations in diet or fluid intake. In the exercise of clinical judgment, in the case of the anemias, the physician has few objective standards that are capable of more than gradual change. One must be extremely cautious, therefore, in delivering a clinical opinion before several weeks have elapsed after symptomatic treatment has been instituted.

Keeping in mind the necessity for observing this skeptical point of view, however, it may be stated at once that the fair conclusions to be drawn from the cases reported below, are, a, that the administration of combined desiccated spleen and red bone marrow offers greater promise of success in the symptomatic treatment of secondary anemia than the administration of iron or arsenic; b, that this preparation would seem to cause a more rapid improvement in the blood picture in secondary anemia than any other agency except transfusion, and c, that it is of no value in pernicious anemia except as a diagnostic aid.

SUMMARY OF CASES

The cases listed here are unselected, and are such as may occur in the general practice of a physician in a medium sized city. The blood counting was done by experienced technicians, using standard methods. The hemoglobin content was estimated by the Dare instrument.

The criteria used as a basis for judging improvement in a case were, a, an alteration in the blood picture for the better; b, a gain in weight, and c, an improved clinical condition. The blood picture was considered "moderately improved" if the erythrocytes increased over 500,000, and if the hemoglobin percentage rose more than ten points.

The total number of patients studied was thirty-two, of whom three showed absolutely no improvement, five gave evidence of slight or questionable betterment, eleven were moderately improved, and thirteen were considerably or markedly helped.

Of the three cases not benefited, one was diagnosed as pernicious anemia, one was a case of inoperable cancer, and the third was shown at the autopsy conducted by Dr. C. H. Bunting to be an example of acute myeloblastic leucemia. Three of the five cases in which improvement was slight or doubtful were senile anemias in women beyond the sixth decade, while one was an anemia secondary to advanced pulmonary tuberculosis, and the fifth was an anemia secondary to severe chronic arthritis of eight years' duration.

Six of the eleven patients who were moderately improved after treatment with spleen marrow compound had long persisting anemias secondary to chronic arthritis, and were women in the fifth or sixth decades. The anemias in these cases had resisted long continued use of iron and arsenic administered separately and combined by different routes. Three of the eleven in this group were cases of chronic anemias secondary to some unknown cause, in whom again, iron and arsenic administered in a variety of forms had been of no value. Of the remaining two cases in the eleven of this group moderately benefited, one was an anemia secondary to empyema, and the other was a severe anemia secondary to dietary irregularities in a young infant.

Of the thirteen anemic patients considerably improved under treatment with combined desiccated

spleen and red bone marrow, four were cases of severe anemias secondary to postpartum hemorrhage, in whom recovery was much more prompt and marked than I had noted in similar cases in whom other forms of treatment (transfusion excepted) had been employed. Three women in this group of thirteen suffered from menorrhagic anemias or anemias secondary to some unknown cause probably associated with disturbed menstrual or sexual function. Two infants (one four months old, the other six) were considerably and apparently permanently improved by a two weeks' period of daily administration of a saline broth made from the spleen marrow mixture. In both these infants, previous attempts to improve the anemic condition by dietary regulation and by other methods, had failed. Two cases of moderately severe anemias in women secondary to some unknown etiological factor, were greately benefited by spleen marrow therapy, after intramuscular injections of iron and arsenic during a period of several months had been without avail. A severe anemia secondary to convalescence in typhoid fever improved remarkably and rapidly under treatment with spleen and bone marrow. When this was suspended, a relapse in the anemic condition was noted, but this was quickly overcome by resumption of the spleen marrow therapy. In this case, intramuscular injections of iron and arsenic failed to take the place of the spleen and marrow combination when the latter was withheld. The final case included in this group of greatly improved anemic patients was diagnosed as chlorosis, although the decreasing incidence of this condition warrants caution in making such a diagnosis. This case, and a few others in this group, may be briefly summarized for the purpose of illustrating the type of response noted to spleen marrow therapy in anemia conditions.

Case I.—A sixteen year old girl, of Scandinavian descent, was sent in from the country to live with relatives in the city, while attending high school. On January 28, 1924, she appeared for consultation, complaining of headache, nervousness, and fatigue. She was pale, volunteered the fact that she felt lonely, and she was found to be underweight. Physical examination revealed nothing significant. Her blood count was: red blood cells, 3,900,000; white blood cells, 8,800; hemoglobin, 35 per cent.

Three five grain capsules of combined desiccated spleen and red bone marrow were given daily. On February 12, 1924, her blood picture was: red blood cells, 4,400,000; white blood cells, 7,600; hemoglobin, 55 per cent. The spleen marrow mixture was reduced to two capsules daily, and she was sent home for a week's vacation in the country. On February 23, 1924, her blood count was: red blood cells, 4,600,000; white blood cells, 7,300; hemoglobin, 78 per cent. The administration of spleen marrow was reduced to one capsule daily. She was last seen March 1, 1924, when her general physical condition seemed better; a gain in weight of thirteen pounds was noted, and her blood picture was found to be: red blood cells, 4,800,000; white blood cells, 7,600; hemoglobin, 85 per cent.

Case II.—An unmarried woman, aged twenty-five, was employed in a tobacco warehouse. She was first seen March 27, 1924, when she complained of a gradual loss of weight, a constant tired feeling, a loss of appetite, a slight but persistent cough, and frequent headaches. Physical examination revealed nothing significant, and a microscopic examination of her sputum was negative. Her blood count was: red blood cells, 2,800,000; white blood cells, 6,600; hemoglobin, 55 per cent. Three capsules of the spleen marrow compound were given daily. On April 11, 1924, her blood picture was: red blood cells, 3,920,000; hemoglobin, 75 per cent. The administration of spleen marrow was reduced to one capsule daily, and the patient was last seen on May 1, 1924, when a gain in weight of seven pounds was noted, and the blood count was found to be: red blood cells, 4,200,000; white blood cells, 7,500; hemoglobin, 83 per cent. The patient stated that her subjective symptoms had disappeared.

Case III.—A married woman, aged forty-seven, had undergone the menopause. She had been under observation during the summer of 1923, having had three severe hemorrhages in four months. On October 16, 1923, her blood picture was: red blood cells, 3,100,000; hemoglobin, 53 per cent. She complained of physical weakness and nervousness. During the following four months she received intramuscular injections of iron and arsenic regularly, together with Blaud's pills by mouth. Her final administration of iron and arsenic was February 9, 1924, when her blood picture was: red blood cells, 3,300,000; hemoglobin, 55 per cent.

On March 18, 1924, she was put upon spleen marrow treatment alone, three five grain capsules daily, and her blood count during the next week showed the following changes:

DATE	ERYTHROCYTES	HEMOGLOBIN
March 18, 1924.....	3,200,000	52 per cent.
March 20, 1924.....	3,800,000	47 per cent.
March 22, 1924.....	3,960,000	55 per cent.
March 25, 1924.....	4,010,000	60 per cent.

The administration of the spleen marrow mixture was reduced to two capsules daily. On April 15, 1924, the blood picture was: red blood cells, 4,600,000; hemoglobin, 80 per cent. The administration of the combined desiccated spleen and red bone marrow was reduced to one capsule daily, and the patient has not been seen since.

Case IV.—A married woman, aged thirty-five, was first seen on April 26, 1924. She complained of loss of weight, fatigue, loss of appetite, and an almost complete cessation of menstruation. Physical examination revealed nothing significant. Her blood count was: red blood cells, 3,200,000; hemoglobin, 60 per cent. After two weeks' treatment with spleen marrow mixture (three five grain capsules daily) her blood count was: red blood cells, 4,100,000; hemoglobin, 82 per cent. The spleen marrow compound was reduced to one five grain capsule daily, and the patient was last seen June 21, 1924, when she reported that normal menstruation had returned and that she no longer became fatigued as easily as formerly. A gain in weight of six pounds was noted and her blood picture was: red blood cells, 4,600,000; hemoglobin, 88 per cent.

COMMENT

It is evident from this small series of cases that spleen marrow therapy as a form of symptomatic

treatment is valuable in the general run of secondary anemias commonly found in ordinary practice. It is of no service in pernicious anemia, unless, as Leake and Evans suggest, it may aid in diagnosis. It has likewise no value apparently in other severe pathological involvements of the hemopoietic system, as illustrated by my failure to get beneficial results in the case of myeloblastic leucemia.

The observations made experimentally by Leake indicate that spleen marrow compound stimulates red cell production in normal humans. The slower rise of the hemoglobin as compared with the number of erythrocytes, under this form of therapy, suggests that some attention should be paid to diet in the effort to furnish material for the formation of new hemoglobin. As indicated by the studies of Whipple and Robscheit (3), this may be accomplished by a mixed diet, with special reference to green vegetables, egg yolks, and meat.

SUMMARY

Desiccated spleen and red bone marrow, combined in equal proportions by weight, and administered in five grain (0.3 gram) capsules, three times daily, constitutes a valuable addition to the armentarium of the physician in the symptomatic treatment of secondary anemia. This form of therapy is more efficient, more rapid in action, and safer than the traditional treatment with iron and arsenic. It is, however, of no service in pernicious anemia. These conclusions are based on a series of thirty-two unselected cases of anemia, observations on which confirm the preliminary report made by Leake and Evans with respect to this form of therapy.

NOTE: I wish to thank the Wilson Laboratories for supplying satisfactory material for use.

The cases included for discussion in this paper do not include six cases studied before January 1, 1924, the observations on which were used by Dr. C. D. Leake and Dr. J. S. Evans for incorporation in a detailed report to appear in the *American Journal of the Medical Sciences.*

FLUID EXTRACT OF CONDURANGO

Its Use in Uterine Hemorrhage, Menorrhagia, Metrorrhagia, and in the Menopause

C. W. MAXWELL, M.D.

Philadelphia, Pa.

Condurango is described as the bark of the Gonolobus condurango, a vine grown in South America. It contains a yellow resin, tannin and two glucosides.

Preparations and dose.—Fluid extract of condurango, dose one fluid dram; wine, dose four fluid drams; decoction, four fluid drams.

Therapeutics.—Condurango was first used in gastric carcinoma and ulcer. It is now known that it has no effect on these diseases, but does allay pain.

A few years ago, on account of the high price of fluid extract of hydrastis and my inability to get the brilliant results from the drug in proportion to the price, my attention was called to the fact that fluid extract of condurango was being used as a stomachic tonic. While I had great need of a stomachic, I had greater need of a drug checking uterine hemorrhages of all kinds. So I proceeded to test it along the same line as hydrastis is used for conditions such as hemorrhage due to fibroids, menorrhagia in the menopause, metrorrhagia, uterine hemorrhages of unknown origin, and hemorrhages caused by cancer of the uterus.

After about eight years' experience with the use of this drug, I find that fluid extract of condurango, given in twenty minim doses every two hours until the required effect is obtained, then less often, is excellent and superior to any other drugs that are used in these conditions.

I consider it a specific in uterine hemorrhage after miscarriage or abortion, in hemorrhage during menopause, in metrorrhagia, menorrhagia, in postoperative hemorrhage, when the bleeding is prolonged after labor, or in any chronic or subacute hemorrhage from the uterus. In short, condurango is indicated wherever the use of hydrastis is advised.

Bleeding from the uterus caused by fibroids can be controlled by condurango longer than by any other drug, and it will act with more dispatch. In cases of old fibroids with bleeding that has gone so long that one despairs to operate on account of loss of blood and weakness, I assert that this drug will control the hemorrhage, tone up the stomach, and always produce a condition more favorable for operation. It causes no pain or discomfort in its action upon the uterus. It does not upset the stomach and is a good alterative.

In cancer of the uterus, it will control bleeding more quickly than any other known drug and its effect is more lasting. I use it exclusively in inoperable cancers of the uterus.

Fluid extract of condurango is nonpoisonous in medicinal doses and its effect is not cumulative. The only strange effect I have ever had from the use of the drug is as follows: In trying to make sure that, in excessive menstruation or bimonthly menstruation, a correct and lasting effect was obtained, the drug was given a good while after bleeding ceased, and the patient skipped the next regular time for her period, but with no ill effects.

I have called attention to the use of this drug to a number of my fellow practitioners who have reported on it favorably.

616 SOUTH FIFTEENTH STREET.

The Use of Salicylates per Rectum.—George R. Irving (*Archives of Pediatrics,* December, 1923) asserts that salicylate in the form of sodium salicylate may be conveniently administered per rectum. The rectal administration may be considered safe in the hands of an attendant with ordinary intelligence or without special training. Relatively large doses may be given once or twice daily—twenty to one hundred grains. By this method of administration, the stomach is particularly free of irritation. In case of untoward effect, the administration of a simple enema will remove the unabsorbed material.

Historical Medicine

The Poet Keats

CHARLES A. CLOUTING, M.D.,
London

Of the English speaking poets none is more of a natural singer than John Keats, one of the glories of English literature. But it is superfluous to dilate on Keats the poet to cultured readers and it will be the object in this essay to give some of the meagre details of his career as a medical student. It may be said that Keats became a member of the medical profession, as he was a surgical student at Guy's Hospital, passed his examination, and was admitted a member of the Society of Apothecaries on July 26, 1816, and, moreover, it is known from various sources that he passed with credit. It has been denied that Keats ever qualified and even the views of many are hazy on this point, but as a matter of fact in his days the license of the Society of Apothecaries was often the only qualification with which the ordinary medical man practised. There was no law in those days requiring a practitioner to have two qualifications as there is now. It may then be taken as proved that Keats qualified regularly but never practised. He is described as a loose, slack, not well dressed youth, with large and lustrous eyes, and hair of golden brown. He was small in stature and his fellow dressers called him "Tiny Keats."

He was born in 1795, the son of a stable keeper, and was a seven months, weakly, puny child, with a constitutional tendency towards pulmonary tuberculosis. When his mother died he came into a legacy of £2,000. From the medical viewpoint the history of Keats begins with his indenture to a surgeon at Edmonton, a suburb of London, to whom the vast majority of would be medical men were apprenticed at that time. He stayed at Edmonton for two years when his articles were cancelled probably on account of a disagreement between the surgeon Matthews and his pupil. The life of a doctor's apprentice was a hard one, and it seems likely that Keats, highly sensitive and impulsive, did not take kindly to the life. It may be recalled that George Crabbe, the poet, was also apprentice to a surgeon in his boyhood and in that capacity was forced to sleep in a barn and run on errands for his master, from whom he learned little medicine and less anatomy.

When at Edmonton Keats made the acquaintance of Cowden Clarke, the well known commentator on the Elizabethan poets, who introduced him to the literary set in London, among whom were Shelley, Haydon and Leigh Hunt. After leaving Edmonton, Keats stayed for some time with Clarke and came up to London. He entered Guy's Hospital as a surgical pupil. In his second term at Guy's, Sir Astley Cooper introduced him to two senior students, one of whom was George Cooper, afterwards demonstrator of anatomy at St. Thomas's Hospital, with whom he went to share rooms nearby Guy's at the house of a tallow chandler named Markham. When his companions left the hospital a few months later Keats shared rooms in the same house with two students of his own year, George Wilson Mackereth and Henry Stephens. Stephens was himself a poet. He remarked that little Keats was fairly popular but was often teased, on account of his pride, his poetry, and even of his birth. It seems that the three friends spent several evenings in literary readings. At these they discussed literary matters, and Stephens has noted that they paid great attention to the opinions of Keats, which were generally diametrically opposed to theirs. Here, too, the poet's brothers frequently visited him, and were highly indignant that his fellow students should make fun of him, since they regarded his poetry as the first flights of genius. In the summer of 1816, Stephens left, and Keats went to live with his brothers, and in the following year went to lodgings in Cheapside.

From 1814 to 1817 little is known of Keats's life, but it is known that he attended Mr. Green's anatomy lectures diligently, of which Mr. Colvin, one of his biographers, has given an interesting account. He states that in the notebook in which Keats took down his own notes of a course or the beginning of a course, of lectures on anatomy, the notes showed no signs of an inaccurate and lax student. The only signs of a wandering mind occur on the margins of one or two pages. Poetry, indeed, had become Keats's chief interest, but it is obvious that at the same time he attended the hospital and did his work regularly, acquiring a fairly solid knowledge, both theoretical and practical, of the rudiments of surgical and medical sciences.

In 1818, writing to his friend Teignmouth, he refers to the books he read in his hospital days as follows: "Were I to study physics, or rather medicine again, I feel it would not make the least difference in my poetry; when the mind is in its infancy a bias is in reality a bias, but when we have acquired more strength, a bias becomes no bias. Every department of knowledge we see excellent, and calculated to a great whole. I am so convinced of this that I am glad at not having given away my medical books, which I shall look over again to keep alive the little I know thitherward." He gives no names of books, but probably among those he possessed were those most in vogue at Guy's then. These were the *London Dissector,* the contemporary Cunningham; Fyfe's *Anatomy,* in three octavo volumes; Innes *On Muscles;* Barclay *On Arteries;* and Saunders *On the Practice of Physics.* Of the larger works, there was Cheselden's magnificent *Osteographie,* with its beautiful plates, hardly, however, a student's book, and Clarke's *On Diseases of Children.* In March, 1816, Keats was appointed dresser to Mr. Lucas. At that time "Calomel" Curry and Alexander Marcet were full physicians. Among Keats's contemporaries may be mentioned Bright, of Bright's disease fame.

The pupils were then classed as apprentices and

ressers, the rule being that each surgeon had four ollowers, of which two at least had to be dressers. A certificate was required from each pupil, signed y his former master, to vouch for the sobriety and noral character of the pupil. Each dresser paid 50 a year, the money being pooled and divided beween the surgeons and the apothecary. There was ne "take-in dresser" who was lodged and boarded t his own expense, and had the right of getting a riend to assist him. After the weekly "take-in" the urgeon who took in waited until his patients were varded and then went round to prescribe for them. No history of the case was taken, but the diet was narked on the ticket. All orders were given verally to the dresser or ward sister. The more inlustrious dressers kept notes of their own cases. The physician, however, acted differently. Each case aving been examined the physician dictated the hisory and the symptoms in Latin, sometimes not first lass, as it is related of a choleric member of the taff who bawled out "*faber Londiniensis* as the quivalent for every Borough occupation. Guy's Iospital is in that part of London known as the Borough district. The students were chary of askng questions for fear of being snubbed.

Each surgeon and his colleague physician vent round twice a week, the former at twelve, the atter at one o'clock. The physicians were more unctual than the surgeons, whose pupils, according o their liking of the surgeons of the day, awaited is arrival in the square in front of the hospital, ome in quiet conversation and not a few in horselay. On the surgeon's arrival the fun ceased. He vas immediately attended by his dressers whose digity was indicated by each carrying a tin plaster box, n shape not unlike a knife box. The surgeons prorided their own instruments, and usually did the first ew dressings after an operation. The only medines used on the surgical side were calomel, Dover's owder and castor oil. The surgeon and most of the upils went round the wards with their hats on.

These sketches of the procedures and customs in ospitals in England in the time of Keats are taken rom the records of one South, who was at Guy's t about the same time. They are put down in this ccount of Keats's medical career because they are nteresting in themselves to medical readers, and ive an impression of the atmosphere in which Keats ived for the greater part of a year.

There are contemporary accounts of his appearnce at that time. A wonderfully mild face, with arge grey brown eyes, a rather pale complexion and wide mouth, a face which in profile showed clearly hiselled lines and marked regularity of features. He dressed shabbily, carelessly, disregarding appearnces as he did opinions, and possessed an amount f moral and physical courage which must have tood him in good stead. At the same time there is vidence of his exceeding mildness of disposition, mildness that amounted almost to shyness as he imself says in surgical work requiring initiative. Writing to Browne he says: "My last operation was he opening of a man's temporal artery. I did it with the utmost nicety, but reflecting on what passed hrough my mind at the time, my dexterity seemed miracle, and I never took up the lancet again." When it is borne in mind that these were the preanesthetic days, and that much less sensitive men than Keats, even a hardened surgeon such as Sir Astley Cooper broke down on occasions when operating, there is little cause for wonder that Keats foreswore the use of the knife. While at Guy's, Keats wrote and composed several of his shorter poems. The exquisite ballad

> Oh, what can ail thee, knight at arms,
> Alone and palely loitering.

is perhaps the only one of his better known poems, that was certainly finished in his hospital days.

At the latter end of 1817 he finally left the hospital, first visiting his friend Clarke with whom he stayed for two months. He then went on a long walking tour, his health having broken down because of his devoted nursing of his brother Tom dying of consumption. He never took up the practice of medicine, although on more than one occasion when his literary prospects looked dark he solaced himself with the thought that his gallipots, to which the Edinburgh reviewers were strongly advising him to betake himself, might yet bring him a livelihood. In spite of the assertions to the contrary and of Byron's fancy that he "was snuffed out by an article," the Edinburgh reviewers, harsh and as it was proved absurd as their criticisms were, had nothing to do with Keats's untimely death.

It is obvious that Keats was in no respect fitted for the life of a medical man. His health, his temperament, his extreme sensitiveness, all conspired to render such a career impossible. On the other hand, there is no reason to suppose that he did not know the theory and to some extent the practice of medicine as well as it was known by the majority of students when they qualified. "It may be," as the writer says in a review of Keats's life published in *Guy's Hospital Gazette* in 1905, "that he went through his hospital course as a discharge of duty he owed his guardian, as many of us do, finding in after life that our true vocation lay in another direction, the law, authorship, politics, commerce, but even then his environment must have influenced him, enlarged his purview and broadened his compassion for suffering and strengthened his pity and charity." But such influence is not shown in his poetry. There is no evidence, direct or indirect, that among the many influences that must have reacted on him his hospital career so reacted. His work or letters are lacking in any references to show that his medical work influenced his poetry. Comments on sickness or hospital life are absent from his poetry. Coleridge and Shelley, both morbidly inquisitive as to medicine and medical matters, have many more direct medical allusions than can be found in the writings of Keats. And yet, as the writer of the article on Keats in the *Guy's Hospital Gazette* says, "though one finds no direct allusions to his medical experiences can anyone honestly doubt that it did not influence him?" For his part he prefers to see, in the restraint of that pathetic sonnet "When I have fears that I may cease to be" in the second stanza of the *Ode to a Nightingale* where he speaks of forgetting—

> that thou hast ever known
> The weariness, the fever and the fret,
> Here where men sit and hear each other groan,
> Where palsy shakes a few, sad, last grey hairs,
> Where youth grows pale and spectrelike and dies.

and in the many other passages scattered through his poems, direct proof of that result and therefore an indirect testimony to the fact that his sojourn at Guy's enriched his mind and was not without effect upon his work. Among those who wrote on Keats was James Russell Lowell.

Keats died from pulmonary tuberculosis on February 21, 1821, barely twenty-six years of age, in Rome, in which city he was buried. He was the *Adonais* of Shelley

> Oh, weep for Adonais—he is dead.
> Like a pale flower by some sad maiden cherished,
> And fed with true love tears, instead of dew.
> The soul of Adonais, like a star,
> Beacons from the abode where the eternal are.

Contributors to the Science of Medicine

René Théophile Hyacinthe Laennec

Théophile Laennec was born on February 17, 1781, in the venerable Episcopal port of Quimper in Brittany, and his birth registered at his baptism the next day in the church of St. Matthew. He was a pure Celt and said to have been descended from the Breton poet, Malherbe. Many members of his family had been lawyers, among them some magistrates. His father was a member of the bar and held several appointments, but because of his capricious temperament was never able to hold for long any position. Sir William Hale-White in his biographical sketch of Laennec describes the father as "a man with a charming manner, a cheerful disposition, good health, much literary culture, always writing poetry, but lacking common sense, proper pride, and genius, he did nothing worth doing with his life." Since he showed not the least aptitude for educating his children, a failing which his friends attributed to the poetic temperament, his little daughter was sent to live with an aunt, and an uncle in Nantes took over the teaching of the two boys. This uncle had practised at Quimper, taken a degree at Paris, studied in England under Hunter, and taken a second degree at the University of Nantes. When the boys arrived he was rector of this university. He, his wife, and his wife's mother soon became devoted to the children, but Théophile was their favorite. The household at that time was composed of the above persons, several servants, a much pampered dog, and a pet parrakeet. The boys were sent to school, and at eleven Théophile adopted the profession of poetry.

Fortunately, his education does not seem to have suffered greatly from the atrocities of the Revolution, of which Nantes was one of the centres. Here, history tells us, three thousand persons were put to death, and, the guillotine being too slow, they were cut down in ranks with chain shot. Men and women were tied together naked and thrown into the river. A permanent guillotine was erected in front of Laennec's house, and the sight of the heads falling was so continuous and terrible that the children were not allowed to look out from the front windows of the house and had to go to school by a back way. The family finally succeeded in getting another house in a more pleasant part of the city. "We come across these two little boys," writes the biographer, "out of bed in the small hours of the morning of June 8, 1794, by the orders of Robespierre, to take part in the Fête de l'Etre Suprême, which began with cannon fire at five a. m., Théophile, then thirteen, wearing a sword."

When their father married again the next year, he wanted the boys to come home to live; but Théophile decided to stay in Nantes and study medicine. His uncle kept him to his purpose through a certain amount of discipline and the encouragement which he needed, combined with protection from conflict with his vacillating father. Théophile, often poverty stricken, would write: "My dear father, I have no longer hat nor shirt, nor a sou in my pocket; if you are as hard up as I am, I am sorry for you; if you are well off, I beg you to send me two louis." Twice he visited his father; once his passage money was delayed for weeks, then the vessel was held by contrary winds, so Théophile landed and walked many miles to Quimper, only to find his father away from home, although the son had been led to believe that he would be there to welcome him. When he did find his father, the latter opposed with all his power his return to Nantes; but the boy's uncle sided with him against the father, and helped him to get away and walk to Nantes. He arrived there after four and a half days, with no money, and thoroughly out of spirits. Sir William Hale-White writes: "The father's parsimony restricted all the pleasures of life, and it needed an uncle out of the ordinary to deal with such a parent, and to help the nephew hampered by these discouragements, and by the disturbed state of mind caused by the constant cannon firing, guillotining, and other horrors of the Revolution. Guillaume successfully and affectionately did both these things. There is every chance that, had it not been for him, Théophile would never have continued his work; therefore it is likely that to Guillaume we owe the blessing of the great Laennec."

In his fourteenth year Théophile entered the School of Medicine at Nantes and diligently attended Bacqua's dissections and anatomical lectures. Even in revolutionary times that a boy of his age could be appointed military surgeon is difficult to believe, but such was the case with Laennec. In 1797 the lad and his uncle went to La Fraternité, where Théophile studied under Ulliac. Here he found time not only for his medical studies, but also for music, dancing, and country walks. Music was his favorite of all the arts, and he learned to play the flute very well. Throughout all these years he was greatly hampered by his father's penuriousness; he had to give up tem-

orarily finishing his course at Paris for this reason. Finally by means of a legal agreement his father was forced to contribute a certain sum for his son's maintenance and tuition in Paris. To save his money, Théophile set out from Nantes for Paris on foot, and, with the help of some lifts, arrived there in less than two weeks. Many men would have been overcome by a much less serious obstacle than the niggardliness of a father who would do nothing to help his son get an education, yet fawned upon him whenever he wished to profit through his son's prominent friends. Laennec had a still greater obstacle to conquer—that of ill health. He was afflicted with asthma, angina, insomnia, neurasthenia, and phthisis.

Yet so rapid was the progress of the brilliant young physician that by 1804 he had been made one of the editors of the *Journal de Médicine, de Chirurgie, et de Pharmacie,* and had been awarded the Grands Prix in both medicine and surgery. His thesis was on *Propositions sur la doctrine Hippocrate relativement à la médecine pratique,* and was a most brilliant contribution; nevertheless Laennec's father refused funds for payment unless his son would dedicate it to someone in a high political position in order that future favors might be solicited. But Théophile remained obdurate and dedicated the thesis to his uncle Guillaume. "This small, attenuated, bony figure of a man, with prominent cheek bones, hollow cheeks, thin nose and lips, calm, reflective blue eyes, a long head covered with carelessly combed, abundant chestnut hair; who was not handsome but not ugly, whose face showed much distinction and intelligence, having gained his degree, was now cast up on the world to earn his livelihood and to illuminate it with genius not often excelled in our profession," writes his biographer.

LAENNEC
(*From a painting by Dubois in* 1812.)

Before long the brilliant young doctor became so busy professionally that he had given up most of his social life, to which he was devoted. He gave up also his editorship and his lectureship because they were a strain upon his delicate health. His father's affairs continued to be a source of great worry and anxiety to him, and he had to pay many of his debts and make him an allowance to live on. By twenty-five, he had reached the high position of the greatest morbid anatomist of his day, and was studying auscultation and conceiving the plan of his great book. Throughout these strenuous and troubled years, Laennec never gave up or forgot his church and charity. He was a devout Roman Catholic and gave his services free to a large dispensary for the poor. In 1814 when Paris was full of sick and wounded soldiers, he volunteered his services to care for them, and collected in his wards all the Bretons who were miserable and homesick, not being able to make themselves understood nor to understand French. Typhus raged in Salpêtrière and two hundred and fourteen deaths occurred among staff members.

In 1819 he was able to give to the world his masterpiece, that great, two volume work entitled *De L'Auscultation Médiate ou Traité du Diagnostic des Maladies des Poumons at du Coeur, Fonde principalement sur ce nouveau moyen d'exploration.* Before this time, medicine, if not empirical, was permeated with metaphysics. Laennec's book was a revelation in that it taught that medicine is a science depending upon observation and experiment. There are many reasons why this remarkable book became at once so famous, among them the fact that it contains perfect descriptions of clinical symptoms and postmortem appearances; it has an account of auscultation with the stethoscope; and its style from a literary point of view is classical.

In 1818 Laennec's health broke down and he retired for a time to his country house in Brittany named Kerlouarnec, "the place of the foxes." Here he soon recovered and returned to his Paris quarters and the care of his faithful maid, Angélique, who took a mother's interest in him throughout the whole of his life in Paris. He was busy again for a year, when his health broke again, with probable incipient phthisis. So he gave up his house in Paris, the good Angélique, sold some of his belongings, and departed once more for Kerlouarnec, where he spent two years caring for the poor, teaching the country doctors, and amusing himself with outdoor sports and occupations. But Paris and his friends and colleagues there called him again, and once more he returned to play the part of successful physician and hearty comrade to his many friends, as well as to receive abuse and ridicule for his medical discoveries. His reputation spread more quickly in foreign countries than in France.

He became again very wealthy, and in 1824 married an old friend, Madame Argou. The early months of his married life were doubtless the happiest of his life, for his wife took care of him and attended to his business affairs. His health improved greatly, but the benefit was short, for soon his feeble constitution gave way again, and he started for his beloved Kerlouarnec with his wife, his cook, and two spaniels. The journey by carriage was long and difficult, and the weather was wretched. Once the coach upset and rolled down an embankment. No one was hurt, but the accident caused a delay of three days for repairs. When they arrived the great physician was so weak that he soon went to bed, from which he never rose again. On August 13, 1826, the end came. He was buried in a place of all others he would have chosen—on a hill overlooking a rugged cliff and an everchanging blue-green sea.

SOME OLD WIVES' REMEDIES

Superstition notoriously dies hard and many of the marvellous remedies devised in days gone by for the ills to which men are heir are still used by the simpleminded in out of the way parts of the country. Some of these remedies are quite of the heroic variety and require a good deal of courage on the part of the sufferer to undergo. However, as one of these treatments is recommended for that insufferable ailment toothache, perhaps wonder at the pluck displayed will be modified when it is taken into consideration that the superstitious family believe in the vaunted cures.

The sympathetic cure advocated in a book entitled *Choice and Experimental Receipts in Physick and Chirurgery* and published in 1668 is as follows: "With an iron nail raise and cut the gum from about the teeth till it bleed, and that some of the blood stick upon the nail; then drive it into a wooden beam up to the head; after this is done you shall never have the toothache in all your life."

Among the many alleged cures for rheumatism, feelingly referred to by Mr. Augustus Birrell as "that worst of all the 'isms," are these. In Holland it is believed that a potato begged or stolen is a preventive, while in certain parts of Northamptonshire it is still held that the right forefoot of a hare kept constantly in the pocket is an efficacious remedy.

The tale goes that some years ago a servant in an old world district of England was found to have been confirmed three times, and on being questioned, said that she had discovered that confirmation was the most efficacious mode of treating rheumatism.

The curing of smallpox in the Middle Ages according to ancient chronicles presented no difficulties. John of Gaddesden, physician to the Court of Edward II of England, adopted the simple expedient of wrapping his patients in red cloth. These are his directions: "Let scarlet red be taken, and let him who is suffering smallpox be entirely wrapt in it, or in some other red cloth; I did this when the son of the illustrious King of England suffered from smallpox. I took care that all about his bed should be red, and cure succeeded very well."

The following original cure for scarlet fever is to be found in an old volume of *Notes and Queries*: "The Irish, when anyone has been attacked with scarlet fever, are accustomed to cut off some of the hair of the sick man, which they put down the throat of an ass. By this means the disease is supposed to be charmed away from the patient and to attack the ass instead." In *Sussex Folk and Sussex Ways,* a book written by the Rev. John Coker Egerton, a strange remedy for goitre is mentioned. "I have known a parson," he writes, "who went a long distance to have a live snake applied to the throat for goitre; and I have known of a servant girl who tried the virtue of a dead one for the same malady. It was discovered, and being obliged to throw it away, she said she would go somewhere and get a dead man's hand to put to her neck."

A MEDICAL POET

It has been proved many times that medicine and poetry are by no means incompatible. A few great poets have been medical men also, although it must be confessed somewhat incidentally. There have been a sprinkling, however, of followers of Æsculapius who have made their living by medicine and in their leisure time have been compounders of very fair verses. The Newcastle apothecary, Peter Pindar, expressed this view in verse admittedly not of a high order:

> And why should this be thought so odd?
> Can't men have taste who cure a phthisic!
> Of poetry though patron god
> Apollo patronized physic.

In England in the time when coffee houses were the vogue several physicians dabbled in verse and gained a fleeting fame as literary men as well as healers. Some of their poetry lives to this day. Among the best of the poet physicians were Garth and Akenside. Garth had a vigorous and sarcastic style while Akenside wrote in the florid amorous manner of the age. Mark Akenside, at any rate, had no doubts as to the inherent incompatibility between medicine and the muses. He was convinced that he was a poet of the first flight and indeed some of his verses were pleasing enough, and such a judge as the great Samuel Johnson ponderously expressed his preference for the work of Akenside to that of Gray. Posterity has reversed this decision to such an extent, that while Gray's fame is established for the ages Akenside is comparatively unknown.

Mark Akenside was born at Newcastle-on-Tyne in 1721. After a brief period of study for the ministry he changed his aims and became a student of medicine at Edinburgh. He took his degree at Leyden in 1744 and came to London, seeking to establish himself in practice with but indifferent success. Yet, he was appointed assistant physician to St. Thomas's in 1759 and two months later succeeded to the senior staff. Lettsom, the well known Quaker doctor, was then a student at St. Thomas's,

and considered Akenside "the most supercilious and unfeeling physician" he had ever known. Lettsom, together with his friend and fellow Quaker Dr. Fothergill, in after years founded the Medical Society of London in 1778. Of him were written the satirical lines:

When folks is sick they comes to I
I physicks, bleeds and sweats 'em;
And, if in spite of that—they die—
What's that to I? I lets 'em.

Smollett, the novelist, who was also a medical man, had been unfavorably impressed by Akenside some time before his election to the hospital, and had introduced into *Peregrine Pickle* a caricature of the poet physician which is sufficiently scathing after due allowance for exaggeration has been made.

Akenside's chief publications were, in 1744, *The Pleasures of the Imagination,* and in 1764 *On Dysentery,* the latter by the way in prose. The following quotation will give an idea of the kind and quality of Akenside's effusions:

I looked, and on the flowery turf there stood
Between two radiant forms, a smiling youth
Whose tender cheeks displayed the vernal power
Of beauty; sweetest innocence illumed
His bashful eyes, and on his polished brow
Sat young simplicity.

THE MODERN NOVEL AND THE PUBLIC HEALTH

More and more the thinking health practitioner is beginning to realize that every activity of the community bears a relation to the community health, that the mental pabulum of the public is as important to its health as its physical food supply, that verminous literature may produce disease processes of the mind and soul just as surely as vermin may transmit the infectious organisms. Thus it becomes the duty of those who are striving to increase the span of useful life to study the work and recreation of the community, its habits of eating and thinking, its index of selfrestraint. In this connection, it is interesting to consider the effect of modern literature, as represented by the printed page and the screen, upon the mental and bodily health of the present and the future.
